Lit Review

Hamilton and Geraci (2006)

IMPLICIT MEMORY: PSE results from conceptual processing of a picture's distinctive features (rather than semantic information). General semantic task: "What is a used car sometimes called?" No PSE. Distinctive conceptual information task: "What fruit is egg shaped?" PSE.

EXPLICIT RECOGNITION: PSE always evident?

aMCI Show larger PSE effects than controls.

Impaired REC, so this PSE must rely on FAM?

Mixed findings whether fam is intact in aMCI. Intact - generally use picture stim. Impaired - generally use verbal stim.

Is PSE in aMCI driven by intact FAM for pictures, but impaired FAM for words? Yes (Embree, Budson, & Ally, 2012): aMCI - Picture FAM - same as healthy OAs aMCI - Word FAM - impaired compared to healthy OAs

Ally, McKeever, 2009: Examined early frontal old/new effect (FAM) in aMCI: Intact for pictures. Impaired for words. BUT, P did not provide subjective Rec/Fam reports.

Embree, Budson, & Ally, 2012: Deep encoding (verbal like/dislike response). Modified Old/New (6-point rating scale): 6. Certain the item is old - to - 1. Certain the item is new.

Both used the same picture stim - colour photos.

Chapter 2

Experiment 1 (Proof of concept)

Research into recognition memory often focuses on methods of estimating recollection and familiarity - two independent processes theorised to support the successful recognition of previously encountered material [Yonelinas (2002); schoemaker2014]. Recollection typically refers to the conscious recall of encoded information, whereby successful recognition is facilitated by contextual details surrounding a previous encounter with the stimulus. Familiarity, on the other hand, is a term used to describe recognition that occurs via an unsubstantiated feeling of having encountered the stimulus previously (despite the inability to retrieve any associated contextual information). While this dual-process model of recognition (Paivio, 1971, 1972)

there remains a disagreement throughout the literature regarding the extent to which recollection and familiarity are independent processes, and the methods used to measure them most effectively.

Experimental paradigms are generally categorized into two broad groups: task-dissociation and process-estimation methods. Task-dissociation methods combine two different task formats (e.g. old/new recognition paired with forced-choice recognition), and make comparisons in an attempt to isolate either recollection or familiarity [yonelinas2002]. Old/new recognition tests are thought to isolate recollection; stimuli are presented individually and participants attempt to make an accurate judgement about items they previously studied (targets) when presented amongst novel items with highly similar characteristics (lures). Forced-choice recognition paradigms, on the other hand, can rely on recollection or familiarity; discrimination between previously studied targets and highly similar lures is again required, however, recognition trials present target-lure pairs at the same time and require that participants select between them.

The wide range of studies utilising process-estimation methods generally use one of three main procedures. First, the process-dissociation procedure (PDP; Jacoby, 1991) is commonly used in recognition memory to separately estimate the contributions of recollection and familiarity by assessing whether participants are able to determine when and where an item was previously studied [yonelinas2002].

Receiver Operating Characteristic (ROC) curves.

Third, and arguably the most commonly used process-estimation method is the Remember/Know (RK) paradigm - a task endorsed by a wide body of literature (Gardiner, 2000; Jacoby et al., 1997; Jacoby, 1991; Tulving, 1985; Yonelinas & Jacoby, 1995). In a typical RK procedure, participants are generally tasked with making an 'old' vs. 'new' recognition decision, before introspectively categorising any recognised items (old) as either 'Remember' when recognition is accompanied by recollection, or as 'Know' when recognition is not accompanied by recollection, but instead is accompanied by a feeling of familiarity or certainty. Often a 'Guess' option is also provided to allow for uncertainty (RKG), in an effort to avoid biasing the total number of R and K responses (Belleville (2011); Gardiner (2008); Gardiner et al. (2002)).

A large body of literature also reports that the RK procedure produces reliable estimations of recollection and familiarity in clinical populations (Lombardi et al., 2016); for example, those with Mild Cognitive Impairment (MCI) typically show recollection impairments but intact familiarity

compared to healthy older adults (Belleville, 2011; Hudon et al., 2009; Lombardi et al., 2016; Serra et al., 2010; L. Wang et al., 2013).

A second method of measurement is to ask participants to make confidence judgements or ratings and interpret high confidence as indicating recollection and low confidence as indicating familiarity. Instead of confidence, some researchers ask participants to make specific ratings of the amount of recollection and familiarity they have for each item they recognise on the memory test; here, rather than a binary Remember-Know judgement which means that the processes of recollection and familiarity are seen as mutually exclusive, in this method recollection and familiarity are viewed as processes that can occur conjointly. Finally, a forth method which uses judgements but permits participants to report that they have both recollection and familiarity for an item is the Recollect-Familiar-Both judgement task. The objective of my research is to better understand what these different methodologies can tell us about the underlying processes of recollection and familiarity. In order to achieve this objective my proposed research will compare different methodologies against each other in different ways: 1. How to define the response options to participants: The way the ‘Know’ response is defined to participants can differ across researchers – some emphasise a feeling of ‘just knowing’ or ‘certainty’, whereas other labs use definitions that emphasise a ‘feeling of familiarity’. I want to know whether how we are defining ‘Knowing’ to participants when we use Remember-Know recognition tests changes how they use the response options. 2. Are ratings tasks better than judgement tasks: Recollection and familiarity or confidence ratings allow for a more fine-grained examination of memory processes but perhaps they are more complicated for participants to use and perhaps they are no more ‘accurate’ than more standard RK judgement tasks? I want to examine how patterns of responding differ across these methodologies.

The RK procedure has been criticized for its reliance on participants’ subjective understanding of the provided instructions (Schoemaker et al., 2014), and the introspective nature of recognition judgements make it difficult to confirm whether all participants have understood the definitions (and thus responded) similarly (Lombardi et al., 2016). Indeed, slight differences in the experimental definition of “knowing” across studies and the way in which the subjective memory states are defined may affect the achieved pattern of results (Geraci et al., 2009; Williams & Moulin, 2015).

The picture superiority effect (PSE) – stimuli presented as pictures are markedly better remembered on tests of recall or recognition than stimuli presented as words (Shepard, 1967).

Studies agree that pictures enhance recollection compared to words in healthy younger and older adults:

Ally & Budson (2007); Ally et al. (2008); Curran & Doyle (2011); Rajaram (1996).

Is the magnitude of this enhanced recollection for pictures consistent across RFG, RFBG, and RFRatings in healthy Ps?

May further demonstrate how the different response options are affecting how people respond (e.g. may reveal if certain conditions over- or under-estimate recollection?)

Are familiarity ratings also better for pics across the 3 conditions?

Is the achieved pattern also evident in healthy older?

What actually is magnitude? Difference between rec for words and rec for pics taken for each group (healthy vs. MCI), and then the difference of those compared??

The magnitude of the PSE is greater in aMCI and AD patients when compared to healthy older (Embree, Budson, & Ally, 2012). Understanding this phenomenon helps to conceptualise how memory breaks down in AD.

However, it has been demonstrated that certain methodological factors can mediate the PSE, at least in certain populations; findings generally show intact familiarity for individuals with aMCI when *pictures* are shown during recognition memory paradigm, but impaired familiarity when word stimuli are utilised (Algarabel et al., 2009; Ally, Gold, et al., 2009; Ally, McKeever, et al., 2009; Anderson et al., 2008; Embree et al., 2012; Hudon et al., 2009; O'Connor & Ally, 2010; Serra et al., 2010; Westerberg et al., 2006; Wolk et al., 2008).

Illustrative

The objective of Experiment 1 was to establish baseline PSE response patterns in younger adults, and examine how PSE magnitudes differ across the three response-option conditions (RF-judgements / RFB-judgements / RF-Ratings). A 2x3 mixed factorial design was utilised, consisting of a within-subjects variable of stimulus type (words / grey-scale line-drawings) and a between-subjects variable of response-option (RF-judgements / RFBG-judgements / RF-Ratings).

Method

Participants

A total of 186 subjects completed the online experiment: 122 females (M age = 26.02 years, SD = 10.04), 60 males (M = 28.1 years, SD = 10.98), and 2 non-binary (M = 19.5 years, SD = 2.121). This sample size is typical in the literature for a medium effect size (.25), however, due to mixed conclusions regarding the direction of R + F, it was difficult to determine an exact a-priori number of subjects.

To meet our YA requirements, all participants were required to be between 18-59 years of age (actual range: 18-59). As our experiment involved English word stimuli, we also asked subjects whether English was their first language; the vast majority (93.01%) reported that English was indeed their first language.

The current sample was primarily comprised of participants sourced from voluntary participation websites such as Prolific Academic¹ (52.15%), where payment at the rate of £5/hr was given, and via the in-school research participation system² (41.4%), where they received course participation credits. A small number of participants were also recruited from social media and other online sources (Facebook: 3.76%; Call For Participants: 1.61%; Reddit: 0.54%; unspecified: 0.54%).

Materials

A random pool of grey-scale line-drawings were sourced from Rossion & Pourtois (2004), along with their corresponding written-word object names (see Appendix XX). All items were imported

¹<https://www.prolific.co/>

²<https://keelepsychology.sona-systems.com/>

into Photoshop CC (20.0.04 Release), where they were converted from their native .bmp file format into .png files. The corresponding written-word items were also created in Photoshop using the Calibri sans-serif typeface and again exported as .pngs. All items were automatically resized and presented at 250x250px by the online survey platform.

Procedure

Data collection was conducted via the online survey platform Qualtrics³. Participants initially completed an encoding phase, where target stimuli (word and picture stimuli) were randomly presented one-at-a-time on-screen. To ensure subjects' directed their attention toward stimuli during the study phase, we utilised a simple encoding question at study: "Is this a picture or a word?". All participants showed a response accuracy of +>90% at study, indicating a high rate of attention toward the presented stimuli. This ability to determine whether participants were concentrating at study is why a blocked design was avoided at study (i.e. separate word / picture blocks); separate blocks for each stimuli-format would make our current encoding question redundant, and whilst we could have used a different question (e.g. "Is this item pleasant?"), we were keen to avoid any aforementioned levels-of-processing effects, whereby deep processing questions may result in ceiling effects for responses made toward picture stimuli.

The encoding phase was followed by a short distractor task, whereby participants completed 20 multiplication sums. This was followed by the recognition task, where subjects were again randomly presented with word and picture items on-at-a-time on-screen, and were required to respond "Old"/"New" depending on whether the recognised the item or not. "Old" responses were succeeded by a follow-up screen whereby participants were asked to report their recognition experience for the current item; the response-options available during this follow-up response page differed between participants, with random allocation into either the RFG, RFBG, or RF-Ratings response-option conditions. Instructions for the memory test were highly similar between conditions, deviating only to explain key changes such as: additional response options (i.e. "Both", in the RFBG condition), and how certain responses should be reported (i.e. 0 on both scales to represent "Guessing" in the RF-Ratings condition).

Data analysis

DVs consisted of: i) the proportion of hits; ii) the proportion of FAs; iii) overall recognition (proportion of overall hits minus proportion of FAs), iv) d' (d-prime; discrimination); v) c (response-bias criterion). Proportions of hits and FAs were also calculated separately based upon follow-up recognition judgements: Recollection, Familiarity, and Guessing. To achieve comparable proportions across each of the response-option conditions - in order to examine the PSE across the different groups - each group had slightly different proportion calculations. For the RFG group, simple proportions were used (i.e. what proportion of hits / FAs were assigned Recollection, Familiarity, and Guessing). For the RFBG group, we separately added the proportion of "Both" to Recollection and Familiarity proportions, since it was defined as representing both processes simultaneously. For the RF-Ratings group, proportions were calculated based on the number of responses above the threshold of +>3; a response was classified as "Recollection" when subjects rated between 3-5 on that particular scale (any Familiarity rating was permissible), and a

³<https://www.qualtrics.com/uk/>

response was classified as “Familiarity” when subjects rated between 3-5 on that particular scale (any Recollection rating was permissible). Guessing responses were calculated as the proportion of responses where participants rated 0 on both scales toward a single item (participants were instructed to respond in this way if their response was a rec).

Note: should we have a performance cut off? Some people have very low performance (like 0 or 1 hits) and should probably be excluded?

Results

Overall hits, false alarms (FAs), and recognition

Separate 2 (stimuli format: words, pictures) x 3 (response-option condition: RFG-judgements, RFBG-judgements, RF-ratings) mixed ANOVAs were conducted on the mean proportion of hits and false alarms (FAs; see Table 1).

Table 1: Mean proportion of hits and FAs by stimuli-format and response-option condition.

	Hits	FAs
Stimuli-format		
Words	0.47	0.21
Pictures	0.62	0.12
Response-option		
RFG	0.62	0.19
RFBG	0.54	0.16
RF-Ratings	0.48	0.14

In the ANOVA on the proportion of hits, there was a significant main effect of stimuli-format, $F(1, 183) = 131.77$, $MSE = 0.01$, $p < .001$; pictures ($M = 0.62$) produced a higher number of hits than words ($M = 0.47$), , supporting the notion that stimuli-format plays a role in item recognition. There was also a significant main effect of response-option condition, $F(2, 183) = 6.46$, $MSE = 0.09$, $p = .002$, with the RFG group ($M = 0.62$) showing more hits compared to the RF-Ratings group ($M = 0.48$), , suggesting fewer available response-options may facilitate accurate recognition. There were no significant interaction effects, $F(2, 183) = 0.35$, $MSE = 0.01$, $p = .707$. Click here to see output: [Appendix A - ANOVA Prop hits][].

The ANOVA on the proportion of FAs also highlights the role of stimuli-format on the memorability of items, with a significant main effect of stimuli-format $F(1, 183) = 61.18$, $MSE = 0.01$, $p < .001$ showing words ($M = 0.21$) produced more FAs than pictures ($M = 0.12$). There was no significant main effect of response-option condition, $F(2, 183) = 2.70$, $MSE = 0.03$, $p = .070$, or significant interaction, $F(2, 183) = 0.51$, $MSE = 0.01$, $p = .603$. Click here to see output: [Appendix B - ANOVA Prop FAs][].

A similar pattern was again reflected in the ANOVA on overall performance accuracy; a significant main effect of stimuli-format $F(1, 183) = 409.20$, $MSE = 0.01$, $p < .001$ revealed that pictures ($M = 0.50$) showed an increased overall task performance accuracy compared with words ($M = 0.27$). There was no significant main effect of response-option condition, $F(2, 183) = 2.85$, $MSE = 0.08$, $p = .060$, or significant interaction, $F(2, 183) = 0.33$, $MSE = 0.01$, $p = .720$. Click here to see output: [Appendix C - ANOVA Overall recognition][].

Discrimination (d') and response bias (c)

To assess the roles of discrimination and response bias, separate 2 (stimuli format: words, pictures) \times 3 (response-option condition: RFG-judgements, RFBG-judgements, RF-ratings) mixed ANOVAs were conducted on d' (d-prime; measure of sensitivity) and c -scores (decision criterion; see Table 2).

Table 3:

	d'	c
Stimuli-format		
Words	0.86	0.53
Pictures	1.62	0.48
Response-option		
RFG	1.35	0.34
RFBG	1.20	0.50
RF-Ratings	1.16	0.67

The ANOVA on d' scores was consistent with the hits, FAs, and overall recognition findings; there was a significant main effect of stimuli-format, $F(1, 183) = 295.80$, $MSE = 0.18$, $p < .001$ showing pictures ($M = 1.62$) facilitated better discrimination between hits and FAs than words ($M = 0.86$). There was again no significant main effect of response-option condition, $F(2, 183) = 1.53$, $MSE = 0.84$, $p = .219$, or significant interaction, $F(2, 183) = 0.25$, $MSE = 0.18$, $p = .778$. Click here to see output: [Appendix D - ANOVA d' (discrimination)][].

In the ANOVA on c -scores, there was no significant main effect of stimuli-format, $F(1, 183) = 2.31$, $MSE = 0.11$, $p = .130$, indicating response bias was unaffected regardless of whether participants were responding to words or pictures. There was, however, a significant main effect of response-option condition, $F(2, 183) = 6.44$, $MSE = 0.51$, $p = .002$; those in the RF-Ratings condition ($M = 0.67$) showed higher c -scores (and thus a more conservative response bias) than those in the RFG condition ($M = 0.34$), suggesting participants were less likely to respond "Old" when they were required to provide more detailed follow-up recognition judgements (Recollection: 0-5 / Familiarity: 0-5), compared to simply selecting one of three

options (R,F, or G). There were no significant interaction effects, $F(2, 183) = 0.14$, $MSE = 0.11$, $p = .869$. Click here to see output: [Appendix E - ANOVA c (bias)][].

Hits assigned Recollection, Familiarity, and Guessing

To determine the effects of stimuli-format and response-option on accurate recognition memory judgements, separate 2 (stimuli format: words, pictures) \times 3 (response-option condition: RFG-judgements, RFBG-judgements, RF-ratings) mixed ANOVAs were conducted on the mean proportion of hits assigned Recollection, Familiarity, and Guessing (see Figure 1).

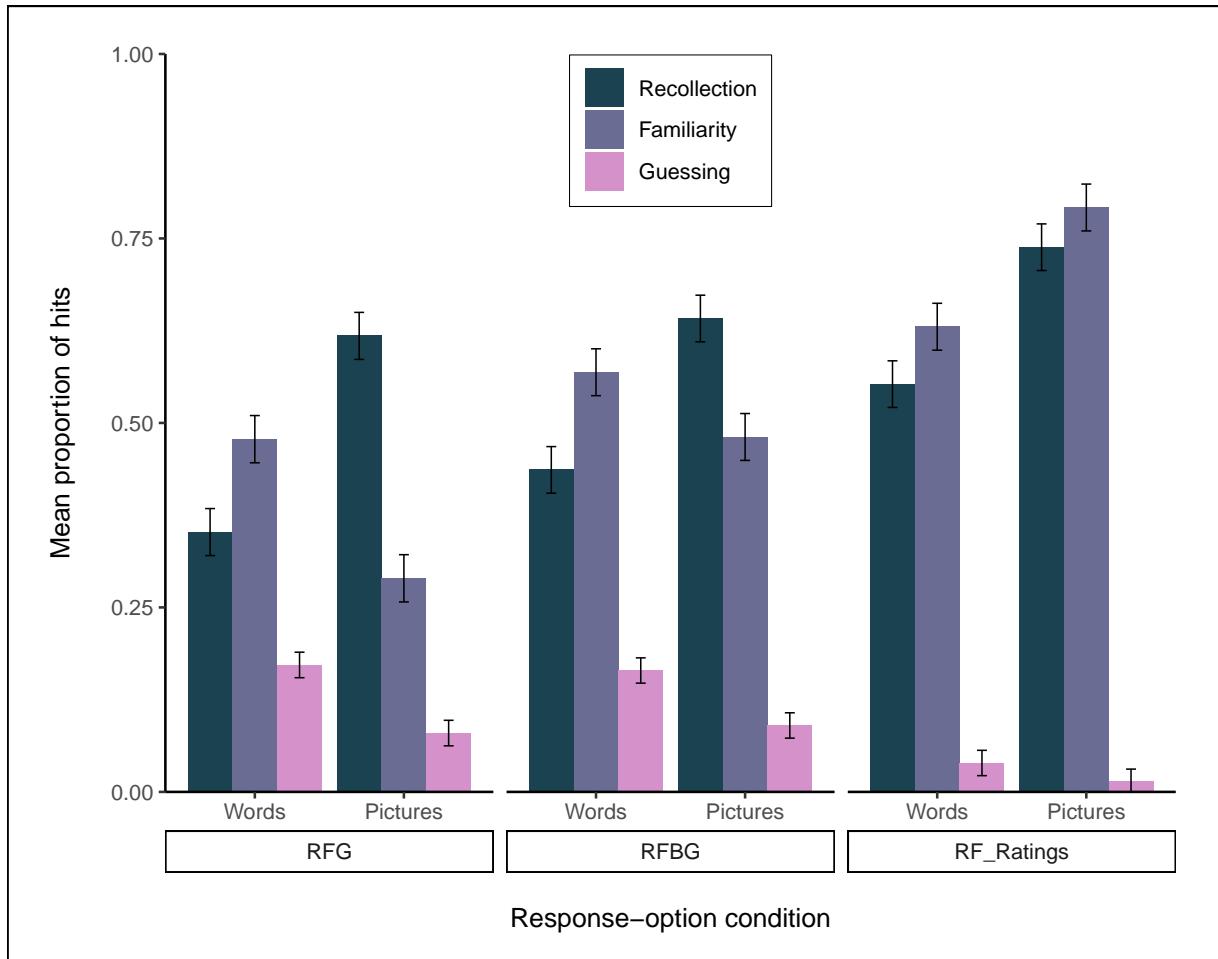

Figure 1: Proportion of hits assigned Recollection, Familiarity, and Guessing, by stimuli-format and response-option condition.

Recollection

The ANOVA on Recollected hits revealed a significant main effect of stimuli-format, $F(1, 178) = 158.42$, $MSE = 0.03$, $p < .001$, with pictures ($M = 0.67$) showing a higher proportion of Recollected hits than words ($M = 0.45$), - consistent with the previous findings to suggest an enhanced memorability in pictures compared to words. There was also a significant main effect of response-option, $F(2, 178) = 8.55$, $MSE = 0.09$, $p < .001$; the

RF-Ratings group ($M = 0.65$) showed significantly more Recollected hits compared to both the RFG-group ($M = 0.49$), , and the RFBG-group ($M = 0.54$), . There were no significant interaction effects, $F(2, 178) = 1.91$, $MSE = 0.03$, $p = .151$. Click here to see output: [Appendix F - ANOVA Rec hits][].

Familiarity

In the ANOVA on Familiarity hits, there was again a significant main effect of stimuli-format, $F(1, 178) = 4.65$, $MSE = 0.03$, $p = .032$; words ($M = 0.56$) resulted in a higher proportion of familiarity hits than pictures ($M = 0.52$), , indicating that - when correctly recognised - words were not recognised in the same context-rich nature as pictures. There was also a significant main effect of response-option, $F(2, 178) = 34.52$, $MSE = 0.09$, $p < .001$, with the RF-ratings group ($M = 0.71$) showing more Familiarity hits than both the RFG-group ($M = 0.38$), , and the RFBG-group ($M = 0.52$), . The RFBG-group ($M = 0.52$) also showed significantly more Familiarity hits compared with the RFG-group ($M = 0.38$),

There was also a significant interaction, $F(2, 178) = 34.42$, $MSE = 0.03$, $p < .001$ (see Figure 2). Within response-option conditions, words resulted in more Familiarity hits than pictures in both the RFG group (words: $M = 0.48$; pictures: $M = 0.29$), $t(178) = 6.07$, $p < .001$; and RFBG group (words: $M = 0.57$; pictures: $M = 0.48$), $t(178) = 2.87$, $p = .005$. Conversely, the RF-Ratings group showed the opposite pattern, with more Familiarity hits produced for pictures ($M = 0.79$) than words ($M = 0.63$), $t(178) = -5.29$, $p < .001$.

Between response-option conditions, word stimuli produced significantly more Familiarity hits in the RF-Ratings group ($M = 0.63$) compared to the RFG group ($M = 0.48$), $t(276.78) = -3.37$, $p = .002$. For pictures, a higher number of Familiarity hits was evident in the RF-Ratings group ($M = 0.79$) compared to both the RFG group ($M = 0.29$), $t(276.78) = -11.13$, $p < .001$ and RFBG group ($M = 0.48$), $t(276.78) = -6.94$, $p < .001$. The RFBG group ($M = 0.48$) also showed a significantly higher number of Familiarity hits compared to the RFG group ($M = 0.29$), $t(276.78) = -4.24$, $p < .001$. Click here to see output: [Appendix G - ANOVA Fam hits][].

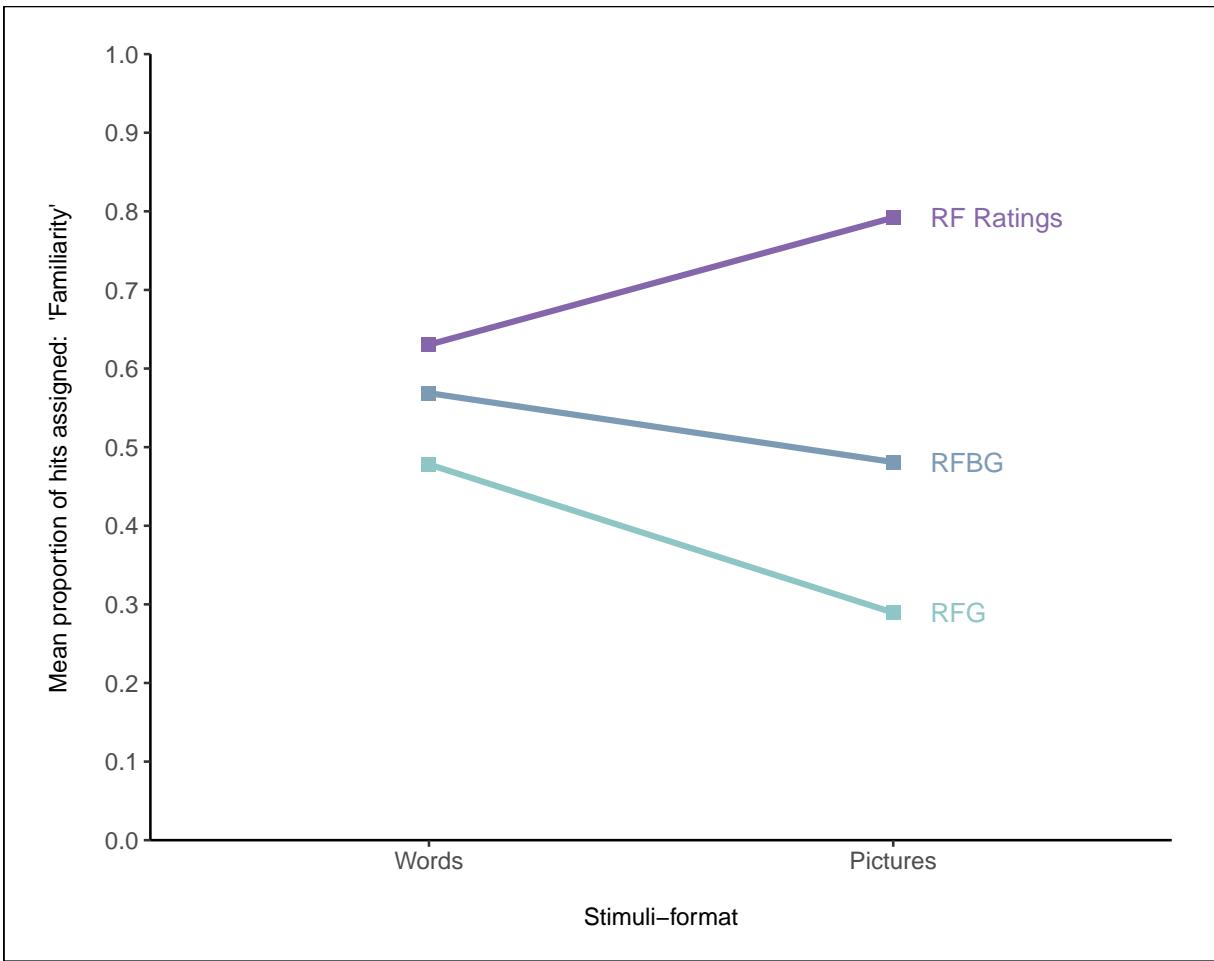

Figure 2: Interaction plot between stimuli-format and response-option condition for the mean proportion of hits assigned 'Familiarity'.

Guessing

The ANOVA on Guessing hits again showed a significant main effect of stimuli-format, $F(1, 178) = 42.84$, $MSE = 0.01$, $p < .001$, with words ($M = 0.13$) showing more Guessing hits than pictures ($M = 0.06$), - a finding that aligns with the results for hits assigned Recollection and Familiarity, whereby words appear to not be recognised in the same context-rich nature as pictures. There was also a significant main effect of response-option, $F(2, 178) = 14.97$, $MSE = 0.03$, $p < .001$, with the RF-Ratings group ($M = 0.03$) showing significantly fewer Guessing hits than both the RFG ($M = 0.13$), , and RFBG ($M = 0.13$) groups, . Despite 'Guessing' responses being permissible in any of the response-option groups, it seems when two independent rating scales were required participants were less likely to report a "Guess". This could be because those in the RF-Ratings condition selected "New" more often than "Old" when they were having a complete guess, or instead, subjects might have opted to report lower levels of Recollection and Familiarity ratings (i.e., 1-3), rather than responding 0 on both scales.

There was also a significant interaction, $F(2, 178) = 4.17$, $MSE = 0.01$, $p = .017$, (see

Figure 3). Within response-option conditions, words resulted in more Guessing hits than pictures in both the RFG group (words: $M = 0.17$; pictures: $M = 0.08$), $t(178) = 5.38, p < .001$; and RFBG group (words: $M = 0.16$; pictures: $M = 0.09$), $t(178) = 4.42, p < .001$.

Between response-option conditions, word stimuli produced significantly fewer Guessing hits in the RF-Ratings group ($M = 0.04$) compared to both the RFG group ($M = 0.17$), $t(281.42) = 5.44, p < .001$, and the RFBG group ($M = 0.16$), $t(281.42) = 5.18, p < .001$. A similar pattern was also evident for pictures, with significantly fewer Guessing hits in the RF-Ratings group ($M = 0.01$) compared to both the RFG group ($M = 0.08$), $t(281.42) = 2.70, p = .020$ and RFBG group ($M = 0.09$), $t(281.42) = 3.15, p = .005$. Click here to see output: [Appendix H - ANOVA guess hits][].

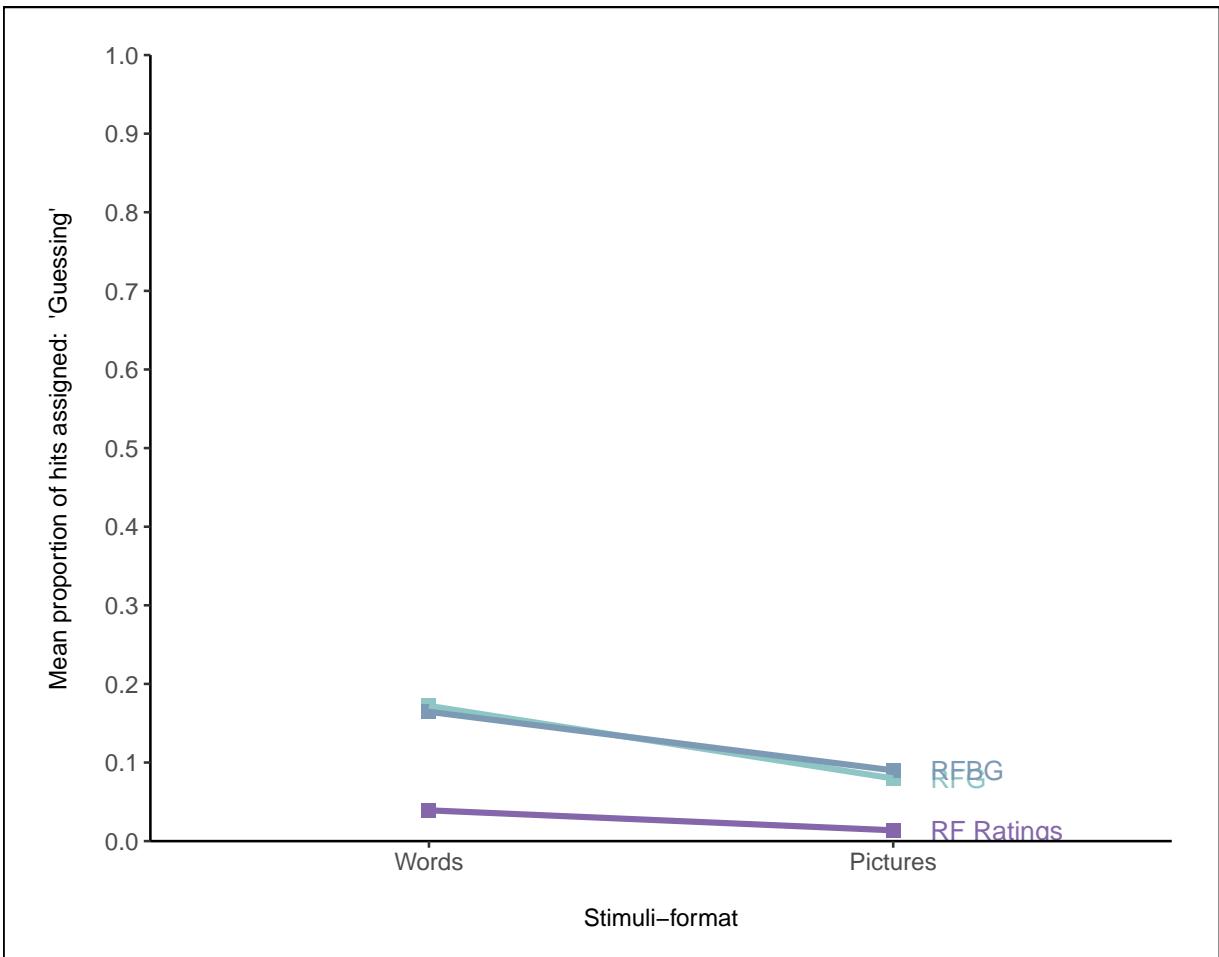

Figure 3: Interaction plot between stimuli-format and response-option condition for the mean proportion of hits assigned 'Guessing'.

False alarms (FAs) assigned Recollection, Familiarity, and Guessing

To determine the effects of stimuli-format and response-option on false recognition memory judgements, separate 2 (stimuli format: words, pictures) \times 3 (response-option condition: RFG-judgements, RFBG-judgements, RF-ratings) mixed ANOVAs were conducted on the mean proportion of FAs assigned Recollection, Familiarity, and Guessing (see Figure 4).

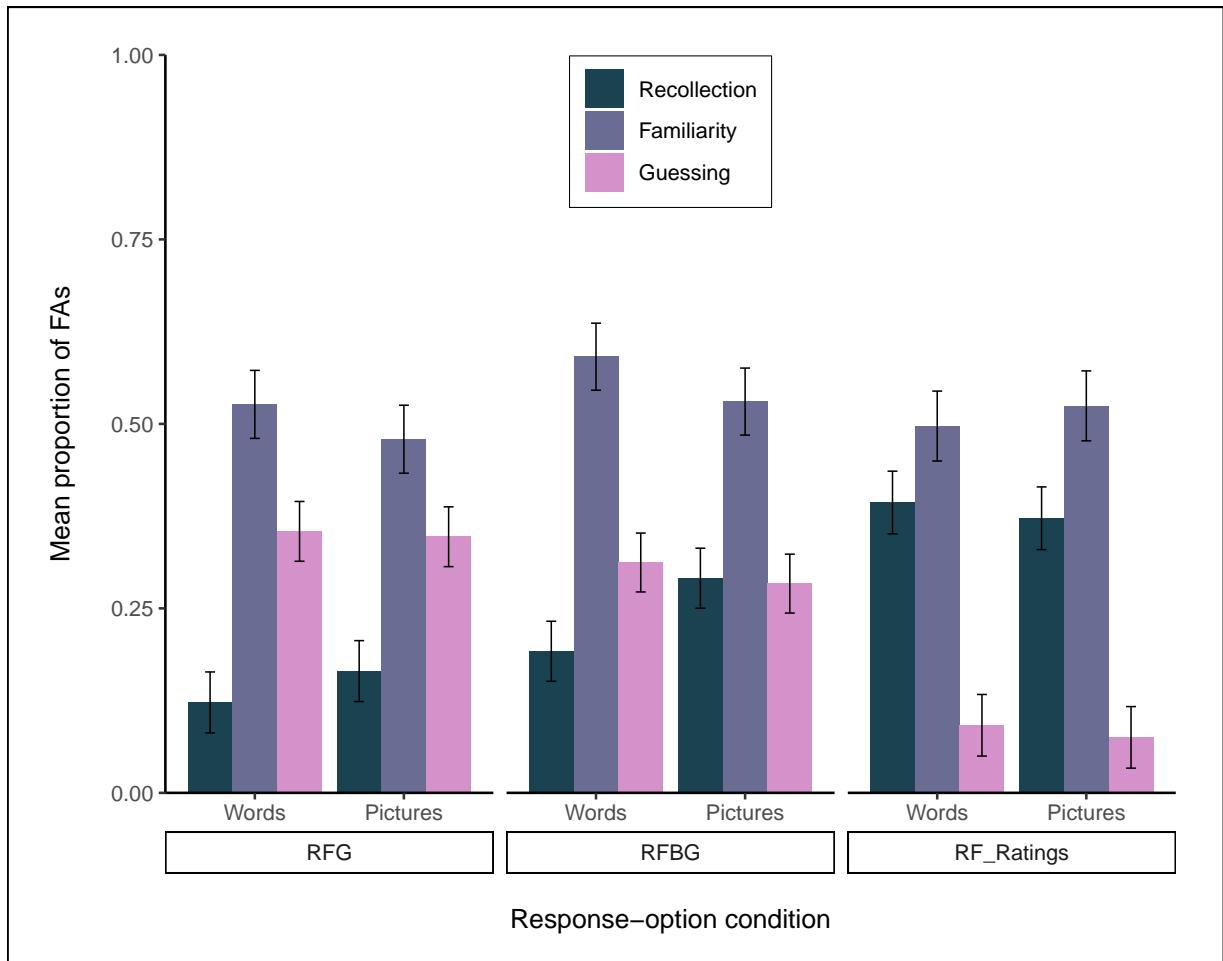

Figure 4: Proportion of FAs assigned Recollection, Familiarity, and Guessing, by stimuli-format and response-option condition.

Recollection (FAs)

In the ANOVA on Recollection FAs, there was no significant main effect of stimuli-format, $F(1, 136) = 2.78$, $MSE = 0.04$, $p = .098$, but there was a significant main effect of response-option, $F(2, 136) = 10.70$, $MSE = 0.12$, $p < .001$, with those in the RF-ratings group ($M = 0.38$) showing more Recollection FAs than both the RFG-group ($M = 0.14$), , and the RFBG-group ($M = 0.24$),).

This could indicate that when subjects were required to individually report Recollection and Familiarity on two 0-5 rating scales, they were more likely to experience (or report) false recognition (accompanied by non-existent contextual details) than when only three (RFG) or four (RFBG) response-options were provided. There were no significant interaction effects, $F(2, 136) = 2.08$, $MSE = 0.04$, $p = .129$. Click here to see output: [Appendix I - ANOVA Rec FA][].

Familiarity (FAs)

The ANOVA on Familiarity FAs did not yield any significant results; with no significant main effect of stimuli-format, $F(1, 136) = 1.12$, $MSE = 0.04$, $p = .292$, no significant main effect of response-option, $F(2, 136) = 0.62$, $MSE = 0.15$, $p = .539$, and no significant interaction effects, $F(2, 136) = 1.12$, $MSE = 0.04$, $p = .331$. Click here to see output: [Appendix J - ANOVA Fam FA][].

Guessing (FAs)

Finally, the ANOVA on Guessing FAs also showed no significant main effect of stimuli-format, $F(1, 136) = 0.51$, $MSE = 0.04$, $p = .476$, but there was a significant main effect of response-option, $F(2, 136) = 15.69$, $MSE = 0.11$, $p < .001$, with the RF-ratings group ($M = 0.08$) showing significantly fewer Guessing FAs than both the RFG ($M = 0.35$), , and RFBG groups ($M = 0.30$), . This again aligns with previous results, suggesting that those in the RF-Ratings group were less likely to report guesses than the other groups, whether accurate or not. There were no significant interaction effects, $F(2, 136) = 0.07$, $MSE = 0.04$, $p = .935$. Click here to see output: [Appendix K - ANOVA Guess FA][].

Discussion

How do colour (vs. greyscale), and illustrations (vs. photographs) differentially affect responses across RFG, RFBG, and RF Ratings?

“perhaps the current study stimulus set of high-resolution colour images may have helped patients overcome visual processing deficits, and use distinctive information to improve memory for pictures over words” - (Ally, Gold, & Budson, 2009) – expected visual processing deficits to manifest as reduced PSE in MCI, but as the results did not support this, suggest the colour images may have helped to bypass this. “Future studies can perhaps examine whether increasing the amount of detail present in a picture enhances discrimination”

Suzuki & Takahashi (1997): recognition performance was highest when colour pictures were used in both the study and test phases (compared with black and white).

Chapter 3

Experiment 2 (Image Norms)

Development of a new set of standardised photographic stimuli

The Picture Superiority Effect (PSE) is a highly robust and replicable phenomenon. In recognition memory paradigms, the PSE has been shown to manifest as both increased recollection and familiarity (Dewhurst & Conway, 1994; Rajaram, 1996, 1993; Wagner et al., 1997; Yonelinas, 2002). The effect is present in children, adolescents and healthy older adults (Whitehouse et al., 2006), though perhaps more striking is the fact that patients with Alzheimer's disease or those presenting early isolated memory impairments, known as amnestic mild cognitive impairment (aMCI), also show memorial benefits toward pictures (Ally, 2012). This is supported by ERP studies demonstrating comparable enhancements to recollection-based ERP components between healthy older and aMCI groups when pictures, rather than words, are utilised (Ally, Gold, et al., 2009). There is debate within the literature attempting to characterise the nature of memory deficits in aMCI, whereby despite general agreement that recollection processes are impaired in such individuals, findings show great inconsistency with regard to familiarity (Algarabel et al., 2012; Belleville, 2011; Pitarque, 2016; Wolk et al., 2011, 2013). The PSE may have been largely overlooked as an area for further research in an effort to help settle this debate, despite recent reviews highlighting methodological differences across studies as the potential source of inconsistent findings (Koen & Yonelinas, 2014; Migo et al., 2012; Schoemaker et al., 2014). The level at which stimuli distinctiveness impacts successful recognition is currently unclear, and there is little consistency across studies with regard to what is considered a 'picture'.

Many experiments utilise illustrations for their picture stimuli (van der Meulen et al., 2012; Westerberg et al., 2013; Wolk et al., 2011), with a standardised set of items published by Snodgrass & Vanderwart (1980) among the most-used illustrated picture stimuli within the domain of memory research (Bermúdez-Margaretto et al., 2018; Deason et al., 2015; Hockley, 2008; Martins & Lloyd-Jones, 2006; McBride & Anne Dosher, 2002; Meade et al., 2019; Schmitter-Edgecombe et al., 2009; van der Meulen et al., 2012; Wagner et al., 1997; Wammes et al., 2016; Weldon et al., 1989; Weldon & Roediger, 1987; Whitehouse et al., 2006). The set consists of 260 line drawings of common, everyday objects (in black ink), along with their written word counterpart (e.g. "shoe"). Items were selected on the basis of exemplifying a number of semantic categories, including animals, furniture, fruit, etc., and a range of normative data was collected for each item; indices of naming agreement, mental imagery agreement, visual complexity, and familiarity were all recorded for each drawing. The normative data for the Snodgrass & Vanderwart (1980) items has been continually revisited, with a number of studies gathering culturally-appropriate norms (e.g. in Spanish (Sanfeliu & Fernandez, 1996), Chinese (Yoon et al., 2004), and Russian (Tsaparina et al., 2011), and additional testing of the relationship between reaction time and naming agreement (Székely et al., 2003). There are multiple theories of object recognition; the recognition-by-components theory proposed by Biederman (1987) identifies shape as the most crucial factor for successful recognition, in which case, the object outlines found in the set by Snodgrass & Vanderwart (1980) should be more than sufficient for experimental cognitive research. Other theories, however, posit that surface details such as colour and texture are just as crucial in forming object representations (Tanaka et al., 2001; Tarr & Bühlhoff, 1998). The wide-ranging applicability of the Snodgrass & Vanderwart (1980) items throughout a number of cognitive disciplines has led to a more recent revision of the items by Rossion & Pourtois (2004).

This revision consists of the exact same objects, digitally re-drawn to include surface textures and shading. Additionally, this set provides greyscale and colour versions for all items, as opposed to the greyscale-only items found in the Snodgrass & Vanderwart (1980) set (see Figure 5 for example items contained in the Snodgrass & Vanderwart (1980) and Rossion & Pourtois (2004) stimuli sets). The Rossion & Pourtois (2004) revision now appears to be favoured over the original Snodgrass & Vanderwart (1980) set among many cognitive researchers (Rollins & Riggins, 2018, p. @ensor2019; Stenberg, 2006; Wolk et al., 2008), almost certainly attributable to the increased detail and ability to choose whether colour is a necessary condition.

Despite their widespread use, line drawings have been criticised for their relative simplicity and lack of realism (Viggiano et al. (2004)), with many researchers favouring the use of photographs as experimental stimuli (Embree et al., 2012; Pitarque, 2016; Troyer et al., 2016, 2012; P. Wang et al., 2013). Photographs of faces are especially useful in research examining emotion and face recognition (Barba, 1997; Bowen et al., 2019; Cui et al., 2016; Herzmann et al., 2018), though a number of common-object photograph sets have also emerged as ecological alternatives to line-drawn items (Adlington et al., 2009; Moreno-Martínez & Montoro, 2012; Viggiano et al., 2004). While the published sets of photographs are undoubtedly useful in a range of cognitive domains, they do not allow us to specifically examine stimuli format as a factor on its own, as the concepts depicted are unique to the set they derive from. In order to make such comparisons, and ensure any differences in performance (e.g. recognition memory ability) are indeed attributable to stimuli format, the objects depicted must be consistent across stimuli formats. The current study presents a new set of photographic stimuli that extend the set of words and drawings provided by Rossion & Pourtois (2004), wherein each of the concepts depicted has been carefully matched across formats. These new stimuli will be utilised throughout a number of planned recognition experiments that aim to systematically compare measures of recognition against different 'levels' of stimuli. The curation of a new set of photographs - carefully matched to other formats - allows investigation into whether picture superiority magnitudes are mediated by the format pictures are presented in. The inconsistent use of different formats across studies has previously made it difficult to reconcile effects obtained in response to drawings with those obtained in response to photographs - an inherent problem when concepts are not matched across format. Normative data for the new set of photographs is also presented, allowing others who also wish to use our photograph stimuli to filter items by measures of naming agreement, mental imagery agreement, familiarity, visual complexity, and colour diagnosticity.

Method

Participants

A total of 377 subjects completed the online experiment (see Table 4 for a breakdown of the gender and age of the sample). This sample size provided 20 data points for each of the five response types, while also ensuring the experiment did not last too long for participants (approx 25-mins). Subjects were recruited from both voluntary participation websites such as Prolific Academic⁴ (where they received payment at the rate of £5/hr), and via the in-school research participation system⁵ (where they received course participation credits).

Table 4: Gender and age (*SD*) of the current sample.

	Gender	N	Age	
Female	196	33.22	(11.28)	
Male	171	33.15	(10.3)	
Non-binary	2	23.50	(-)	
Unspecified	5	29.40	(6.11)	
Total	377	NA	NA	

To meet our YA requirements, all participants were required to be aged between 18-59 years (actual obtained range: 18-59 years). As our experiment involved typing the English labels for a range of image stimuli, subjects were also asked whether English was their first language; all but one participant indicated that English was indeed their first language (99.2%).

Materials

A pool of 136 line drawings (Rossion & Pourtois, 2004) - depicting common, everyday objects - were brought forward from the previous experiment. These items (along with their written-word labels) would form two of the unique stimuli formats that would be used in future recognition experiments (words and drawings). In this study, the drawings from Rossion & Pourtois (2004) were simply used as a reference in the photograph matching process. Corresponding photographs were obtained online with the aim of depicting the everyday objects in a similar manner to the drawings. The inherent subjectivity involved in this process may have led to images that were not a reliable ‘match’ to the concepts they were selected to depict (for example, the photograph chosen to depict the concept “bottle” may inadvertently provoke the majority of participants to give the label “wine”, thus indicating that this particular photograph fails to accurately depict the intended concept). To address this issue, and ensure all photographs more objectively depict the same concepts as the line drawings, three different photograph variations were found for each everyday object, with the aim of taking the best ‘match’ forward. An emphasis was placed on variety across these variations, with the aim of obtaining at least one photograph that very closely resembled the line-drawn depiction, and another offering a more modern depiction. Some items were substituted due to unique restrictions that meant they could not easily be translated into photographic format (for example, the shapes “arrow” and “star” can not be represented similarly as photographs). Photo stimuli were obtained by searching open-source,

⁴<https://www.prolific.co/>

⁵<https://keelepsychology.sona-systems.com/>

copyright-free image websites (e.g. Unsplash⁶; Pexels⁷) for photographs that depicted the same everyday objects as the line drawings (see Appendix B for the full list of image references).

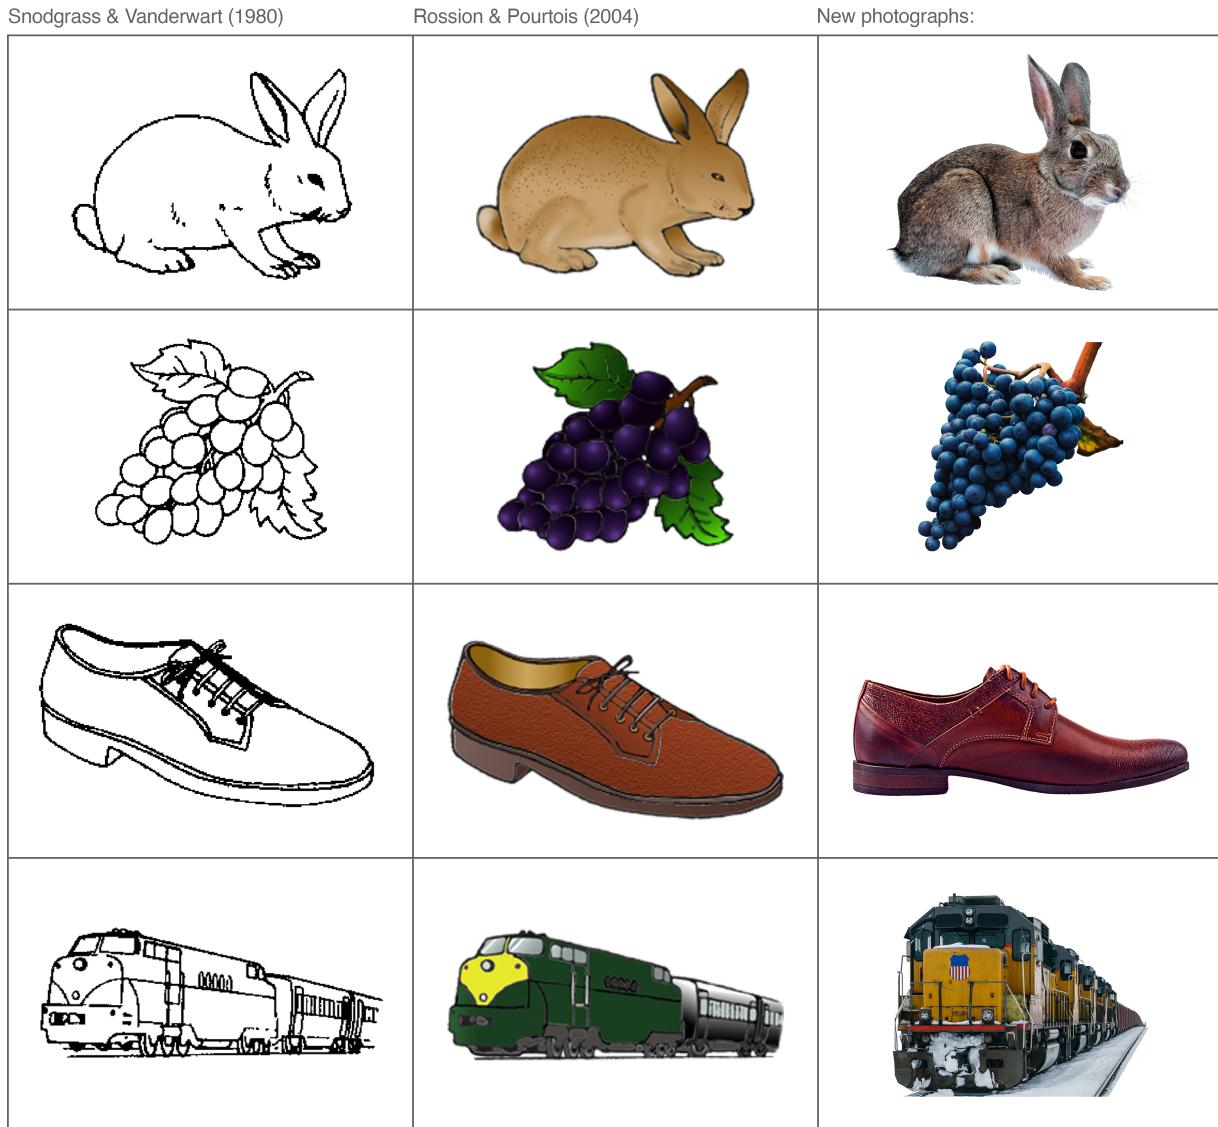

Figure 6: Examples of matching pictures across Snodgrass & Vanderwart (1980), Rosson & Pourtois (2004), and photographs from the current study. Greyscale versions of the drawings and photographs are not presented in this example.

The matching process produced a total of 408 unique photographs. All were imported into Adobe Photoshop (20.0.04 Release), where the background was removed to isolate the object of interest from other potentially distracting visual details. This was completed manually using the magnetic lasso and polygonal lasso tools (edges were either feathered by 1px or left unfeathered). The orientation of isolated objects was adjusted to ensure they matched as closely

⁶<https://unsplash.com/>

⁷<https://www.pexels.com/>

as possible with their line-drawn counterpart (e.g. all photograph variations of the item ‘boot’ were adjusted so the toe was facing left and the heel facing right, as in the line drawing); this was often achieved by flipping or mirroring the object to ‘correct’ the direction.

Despite isolating objects from their background, a small number of photographs still contained irrelevant and potentially distracting details. For example, in one photograph variation of the item ‘piano’, there was a sign on the object that may have impacted how the item was named or rated. Such details were removed as best as possible using the clone stamp and content-aware fill tools. Any obvious text (e.g. brand names) and numbers were also removed from photographs using the same method (see Figure 7). The primary aim of the current study was to obtain photographs that could be clearly distinguished as a unique stimuli format among words and line drawings; it is conceivable that combining these formats (i.e. inadvertently including photographs that also contain written words) might affect recognition performance in ways that are not directly comparable to items defined only by a single category. Any text in our photographs was therefore removed, apart from a couple of exceptions whereby such details happened to be integral to the depiction of the object (e.g. the numbers found on a ruler or clock).

All photographs were exported from Photoshop in “.png” format in both their original colour and in greyscale (by setting saturation levels to 0). Final edits were completed in Adobe Lightroom (Classic, 8.2 Release): exposure (brightness) adjustments were made on images that appeared too light or too dark; highlights were decreased if some areas were too bright compared to the rest of the photograph; shadows were raised if some areas were too dark compared to the rest of the photograph; noise reduction was applied to some items after isolating the subject had inadvertently made unwanted noise/grain more visible. The changes made to each image were systematically applied to both the colour and greyscale versions (e.g. if one variation of “shoe” had an exposure increase of .010 for the colour version, the greyscale version also received an exposure increase of .010). Some colour-specific adjustments were made to the colour photographs only, however; common photo artefacts such as chromatic aberration (purple fringing) were corrected, along with white balance normalisation. Finally, all photographs were placed on a 600x600 pixel white background, and made to fill this frame as much as possible (i.e. some items were restrained by height, whilst others were restrained by width).

Original

Manipulated

Figure 7: Examples of background and text removal in photograph items.

Design

This was a descriptive study; a mix of qualitative and quantitative data were gathered. Across three blocks, all participants provided five types of response toward photograph stimuli: i) Naming; ii) Familiarity; iii) Visual Complexity, iv) Colour Diagnosticity; and v) Mental Imagery Agreement. Excluding the Naming task (consisting of a typed single-word answer), all responses were provided on a 5-point ordinal scale. Within participants, the maximum number of response type provided for any one item was two; Naming and Familiarity responses were paired in one block, Visual Complexity and Colour Diagnosticity responses were paired in another, and Mental Im-

agery Agreement responses were always presented in a separate block. The order of these three blocks was counterbalanced across participants. Toward each individual photograph, participants made only one or two types of response before moving on to the next item, and the same items were not repeated to participants. For each photograph, the five types of required data were obtained by counterbalancing between participants (e.g. for the first variation of the “cat” photograph, the Naming and Familiarity data was obtained from one participant, the Visual Complexity and Colour Diagnosticity data was obtained from another, and the Mental Imagery Agreement data was obtained from another).

Procedure

Data collection was conducted via two online platforms; i) Qualtrics⁸ - a survey platform that allowed for straightforward collection of consent, demographics, and computer compatibility data, and ii) Pavlovia⁹ - an open-source experiment hosting platform for studies programmed in Javascript (Peirce et al., 2019).

In the Naming and Familiarity block, participants were first asked “What is the name of the item depicted?”. Subjects were instructed to name each photograph as briefly and unambiguously as possible, with one name only, and respond by typing their answer into the response box. If they did not know the name of an item, or had a tip-of-the-tongue experience, participants were instructed to type “no” for their answer (the term “don’t know” was avoided so as not to encourage subjects to deviate from single-word responses, as instructed). Following the naming judgement, with the same photograph still present on-screen, participants were next asked “How familiar is the item depicted?”. Subjects were instructed to judge each photo according to how usual or unusual the item was in their realm of experience; specifically, familiarity was defined as “the degree to which you come in contact with, or think about, the concept”, and encouraged participants to rate the concept itself rather than the particular way it was currently shown. Participants selected one value from the 5-point scale, ranging from very unfamiliar (1) to very familiar (5), and were encouraged to use the full range of the scale throughout the set of photographs.

In the Visual Complexity and Colour Diagnosticity block, participants were first instructed to respond to the question “How visually complex is this picture?” using a 5-point scale that ranged from “very simple” (1) to “very complex” (5). Complexity was defined to subjects as “the amount of detail in the picture”; in contrast to the familiarity ratings, participants were encouraged here to rate the complexity of the picture itself, rather than the real-life item. If the photograph shown was greyscale, subjects would simply move on to the next item. If the item shown was in colour, however, participants were also required to make a colour diagnosticity judgement. This concept was defined as “how typical / normal the colour of the item is”, instructing subjects to rate on a 5-point scale ranging from “Not at all diagnostic (i.e. this item could be in any other colour equally well)” (1) to ”Highly diagnostic (i.e. this item appears only in this colour in real life)”. Participants were instructed to utilise the full range of options on the scale when making visual complexity and colour diagnosticity judgements. After making these ratings, a fixation cross was presented during a 1s interstimulus interval.

Due to the slight change in procedure and increased task complexity, Mental Imagery Agreement ratings were always acquired in an individual block (i.e. not alongside any other response types).

⁸<https://www.qualtrics.com/uk/>

⁹<https://pavlovia.org/>

First, participants were presented with a written label for 3s (e.g. “cat”) and told to focus their attention on the word. Once the written word disappeared, a beep tone was played alongside the instruction “close your eyes and imagine this item” (subjects were encouraged to close their eyes and begin imagining the item as soon as they heard the tone, but the written instruction were included as a further prompt). After 3s a second beep tone sounded to alert subjects to open their eyes, where they were presented with a photograph of the item they had been instructed to imagine. On a 5-point scale, participants were asked to “rate the agreement between your mental image and the picture”, from “low agreement” (1) to “high agreement” (5). The degree of agreement was defined as “how similar your mental image of the item is to the picture shown”. A fixation cross was displayed for 1s before the next word item was shown.

All responses were self-paced; the timing was only controlled during the study/imagine section of the Mental Imagery Agreement block.

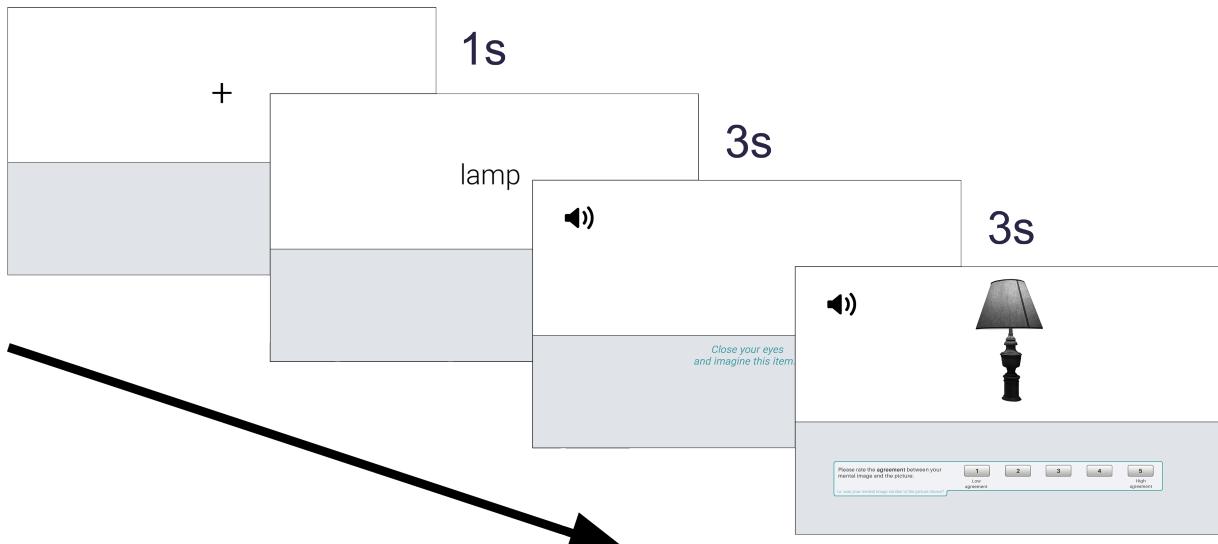

Figure 8: Data collection procedure for Mental Imagery Agreement responses.

Data processing

The naming responses for each photograph item were manually assessed for spelling and typing errors. Automatic spell checking software was avoided in an effort to avoid inadvertently introducing unique names that were not actually given by participants. The vast majority of errors were unambiguous and easy to correct (e.g. “anker” = “anchor”, “peguin” = “penguin”, “ssnowman” = “snowman”), or consisted of transforming plural words to singular (or vice versa, depending on the form of the intended label - e.g. “sock” to “socks”). Some responses were a little more ambiguous, and necessitated comparison to the photographs they were in response to for additional clarity (e.g. a photograph depicting a plug that would fit into North American electrical sockets was labelled as “usplug” - given the nature of our UK-based sample, it’s likely the subject was responding: “U.S. (i.e. United States) plug”).

There were instances where subjects provided a sensible and correctly spelled English word, but that were clearly typos when examined against the photograph they were in response to

(e.g. “dock” for a photograph depicting a duck, “frock” for a frog, and “beer” for a “bear”, etc). The most ambiguous spelling error to correct was “bittle”, which was provided by more than one participant and to more than one item; separate inspections of the photographs participants were responding to made this easy to correct though, with one participant clearly meaning to respond “bottle”, whilst the other meant to respond “beetle”. Though participants were instructed to only give a single label for each item, some multiple word responses were found (without spaces) during the spell checking process. On such occasions, a judgement was made regarding whether multiple words were retained, or whether the response could be shortened into a single word. A general rule was applied whereby if the other words provided additional information, they were retained (e.g. “maledear” - presumably “male deer” - was kept as a two-word answer). Multiple word responses were generally shortened into a single word when the intended label for the item was clearly present, and no information was lost in the process (e.g. “haircomb” was shortened to the intended answer “comb”). It is noted that there was some inherent subjectivity in this process, though as such items were not common among straightforward responses, their overall effects are estimated to be negligible.

Finally, there were some responses that were changed to “no” as they were clearly intended to signify that the responder did not know the name of the item shown; the experiment instructed participants to type “no” in these instances, though the labels “none” and “idk” (common abbreviation for “I don’t know”) were provided instead. There was also a single response that was manually changed to “no”, as the provided label was a single letter and thus entirely unclear what the intended answer should be (see Appendix A for full list of manipulations to naming responses). This process yielded data that could be used to determine which photograph variation best matched the intended concepts (e.g. 100% of participants labelled the object “bottle”, indicating a perfect match), and which did not (e.g. only 50% of participants labelled the item “bottle”, whilst the other 50% gave the label “wine”, indicating a poor match). Photographs showing poor agreement across participant-generated labels, or those where the majority of labels differed from the intended concept, could be replaced with the variation demonstrating the most accurate depiction.

Analysis preparation

A number of variables were calculated prior to analysis. For familiarity, visual complexity, colour diagnosticity, and mental imagery agreement, mean ratings were calculated for each (see Appendix B). Mean reaction times (RTs) were also calculated for each photograph / response variable, including naming responses. For naming responses, accuracy was defined as the proportion of subjects reporting the correct/intended label for any given item (e.g. 80% of subjects correctly labelled a photograph of the moon as “moon”). Percentage agreement was also calculated (i.e. the proportion of subjects providing the most frequent name, regardless of whether it matched the correct/intended label) in order to compute H values for each item. The H statistic also reflects naming agreement, but it takes into account the total number of unique labels given for an item. This is especially useful for comparing similar items, as it captures information not provided by simple agreement proportions. For instance, if the first variation of the photo moon ('moon-1') demonstrated 90% naming agreement among subjects, and the second variation ('moon-2') also demonstrated 90% naming agreement, it would appear as if both versions offer the same level of agreement among participants. However, 'moon-1' may have received a total of 2 unique names (e.g. moon, planet), while 'moon-2' received a total of 4 unique

names (e.g. moon, planet, earth, comet). H values utilise this useful information to determine which item shows the best naming agreement (in other words, the item with the least number of unique names). The original formula by Snodgrass & Vanderwart (1980) was used to calculate H values:

$$H = \sum_{i=1}^k p_i \log_2 \frac{1}{p_i},$$

A H value of 0 indicates perfect naming agreement (all subjects responded with the same label for that item). Items showing a H value of 1 signify two unique names were provided, with identical proportions (e.g. 10 subjects responded “moon” and 10 subjects responded “planet”). As the H value increases, overall naming agreement decreases.

Results

Summary statistics (mean and SD) for each of the measured variables are shown in Table 5. Data for the grey and colour photographs are presented alongside previously obtained normative values for a number of other stimuli formats (all obtained from Rossion & Pourtois (2004), who published revised norms for Snodgrass & Vanderwart (1980)’s (S&V) original line drawings, as well as their own re-drawn versions that contained shading and texture detail). The data from previous studies were not used in any statistical analyses. To examine whether the grey and colour photographs from the current study demonstrated any differences, a series of independent samples t-tests were run on each variable, as well as their corresponding reaction times (excluding scores of colour diagnosticity, which were obtained only in response to the colour items and thus cannot be compared). Mean (and SD) values for all x816 unique photograph items are presented in Appendix B.

Naming

Naming accuracy was very high for all photographs ($M = 0.95$), indicating that overall, the selected items closely depicted the intended concepts. Compared with the other stimuli formats, there appears to be a steady increase in accuracy as items become more distinctive (see Table 5). Accuracy rates did not differ between the grey ($M = 0.94$) and colour ($M = 0.95$) versions of the photographs [$t(745.64) = -0.56, p = .576$].

H values were also low across all items ($M = 0.23$), showing that subjects generally agreed on how the items should be named. Similar to naming accuracy, naming agreement also appears to steadily increase as items become more distinctive (as indicated by decreasing H values - see Table 5). While Rossion & Pourtois (2004) observed significantly better naming agreement for their colour - rather than greyscale - items, this pattern did not reach significance with the current set of photographs; H values did not differ between the grey ($M = 0.24$) and colour ($M = 0.22$) photographs [$t(743.66) = 0.62, p = .537$].

A mean reaction time (RT) of (3.9s) was observed for naming responses. While this was of little interest on its own, and could not be compared to those obtained in response to the other stimuli

formats as our methodology was slightly different (RTs were only recorded when subjects had typed their response *and* clicked the mouse to signify they had finished), they were useful for marking comparisons between the grey and colour items (though no difference was observed [M grey = 4s, M colour = 3.8s, $t(651.86) = 1.57$, $p = .117$]). Overall, these analyses suggest that the current photographs closely resemble the drawings they were designed to match, with high levels of naming accuracy and agreement among subjects. The absence of any colour differences indicates there were no naming advantages when photographs were made even more distinctive through the addition of colour.

Table 5: Summary statistics for each of the measured variables. Mean values are presented in bold (SDs are shown in parentheses).

	Rossion & Pourtois (2004)			Current study	
	S&V lines	Grey shaded	Colour shaded	Grey photos	Colour photos
Naming accuracy	88.2 (17.1)	89.2 (17.2)	90.3 (16.9)	0.94 (0.08)	0.95 (0.08)
Naming agreement (H)	0.44 (0.56)	0.38 (0.52)	0.32 (0.46)	0.24 (0.33)	0.22 (0.31)
Mental imagery agreement	3.73 (0.48)	3.76 (0.55)	3.74 (0.63)	3.46 (0.56)	3.74 (0.65)
Familiarity	3.59 (0.94)	3.52 (1.01)	3.44 (1.01)	4.13 (0.56)	4.19 (0.54)
Visual complexity	2.76 (1.03)	2.88 (1.03)	2.7 (0.94)	2.87 (0.62)	3.16 (0.63)
Colour diagnosticity	-	-	-	-	3.22 (0.84)

Mental imagery agreement

Scores of mental imagery agreement were moderate across all items ($M = 3.6$). While no colour differences were previously observed between stimuli formats, the grey ($M = 3.46$) photographs in the current study showed significantly lower mental imagery agreement scores than the colour ($M = 3.74$) items [$t(800.06) = -6.54$, $p < .001$]. Comparisons with previous normative data also highlight how the grey photographs exhibited uniquely poorer mental imagery agreement scores than any of the other stimuli formats (see Table 5). RTs between the grey ($M = 3.04$) and colour ($M = 2.81$) items did not significantly differ [$t(571.37) = 2.14$, $p = .033$].

Familiarity

Familiarity scores were high overall ($M = 4.16$), and like previous findings, there was no difference between the grey ($M = 4.13$) and colour ($M = 4.19$) items [$t(813.19) = -1.63$, $p = .103$]. However, familiarity scores for the current set of photographs were higher than those obtained for any of the other stimuli formats, and while there previously appeared to be a decline in familiarity as stimuli become more distinctive (from line drawings, to grey shaded, to colour shaded), such a pattern was not evident with the current photographs (see Table 5). RTs between the grey ($M = 0.97$) and colour ($M = 0.98$) items did not significantly differ [$t(783.66) = -0.30$, $p = .762$].

Visual complexity

Visual complexity ratings were moderate across all of the items ($M = 3.3$). Colour ($M = 3.16$) photographs showed significantly higher scores of visual complexity than grey ($M = 2.87$) photographs [$t(813.51) = -6.65$, $p < .001$]. This finding is further demonstrated when compared to the scores from the other stimuli formats (see Table 5); where grey photographs show comparable levels of visual complexity, the colour photographs show higher scores than all of the other formats. There was no significant difference between the RTs of grey ($M = 3.26$) and colour ($M = 3.35$) items [$t(754.08) = -1.21$, $p = .228$].

Selection of final items

For each concept represented in the photographs, one variation (e.g. shoe-1, shoe-2, or shoe-3) was selected for inclusion in a final list of stimuli that would be taken forward into subsequent recognition experiments. The normative naming data was assessed to establish which version best matched the existing line-drawn depictions of the concepts (Rossion & Pourtois, 2004). Naming was favoured over all of the other variables as, if an item was found to primarily convey a different concept than was intended during the naming task (e.g. if a photograph of the fruit ‘orange’ was labelled ‘grapefruit’ by the majority of subjects), then it could not be sufficiently compared to its line-drawn (and written-word) counterpart during recognition studies.

At least 20 unique naming responses were collected for each of the 816 photographs (408 grey items and 408 colour items). The proportion of ‘correct’ responses (i.e. names that were congruent with the intended concept) and the proportion of ‘don’t know’ responses were calculated for each item. Photographs were excluded if they:

1. received a high proportion of “don’t know” responses (20%; all of the photographs depicted common, everyday objects, and so if a number of subjects were unable to name the item, that particular photograph was considered to be a poor representation of the item);
2. were incorrectly named by the majority of subjects (i.e. if the proportion of correct responses equalled $\leq 50\%$, since it was essential for the photographs to depict the same concepts as those found in the line drawings and word stimuli);
3. had particularly poor naming agreement ($\leq 20\%$ subjects named the object similarly). Items may not have been flagged by the second criteria (e.g. if it received 4 different names, each with a 25% ratio), but could still be considered poor representations of the intended concepts.

54 photographs were found to meet at least one of the above criteria, and therefore excluded. Regardless of whether these items were grey or colour, it was also necessary to remove its grey or colour partner (since both versions were needed to make comparisons across recognition experiments). Thus, a total of 64 items (32 grey / 32 colour) were excluded at this stage (many items already had both grey and colour versions flagged by the original criteria).

Next, the proportion of correct responses were compared between grey and colour photographs in order to identify items showing the lowest difference. In order to manipulate colour in later recognition experiments, it was important to select items where naming was congruent across colour/grey items; in other words, it would be difficult to attribute particular recognition response patterns to the addition of colour (if a difference were found) when the grey version could not be identified (or encoded) similarly. Variations exhibiting the least difference between colour and grey items (for the proportion of correct responses) were taken forward, while the rest were excluded. In a number of instances, multiple variations for the same object had the same ‘difference’ score. For example, all three variations of the item “balloon” exhibited perfect naming agreement, irrespective of whether they were presented in colour or grey (and thus “balloon1”, “balloon2”, and “balloon3” had a difference score of 0). For items where more than 1 variation remained, manual rankings were obtained from two of the researchers to determine which variation best depicted the intended concept. For each item, the researchers independently studied the remaining variations and provided a rank of which they thought was best (1) to worst (2 or 3, depending on the number of variations that remained). The ratings from both researchers were collated; items where there was agreement as to which variation best depicted the intended concept were selected for inclusion in the final stimuli list. For all the items where there was disagreement between the researchers rankings, one of the variations was simply selected at random.

Discussion

The role of colour

For naming responses (accuracy, agreement [H], and RTs), no differences were observed between the grey and colour photographs. Such a result was expected for accuracy and agreement scores; the addition/absence of colour should not alter how participants identify (and thus label) items, except in rare instances whereby a lack of colour may lead to the misidentification of an object (e.g. incorrectly labelling a greyscale photograph of an orange as ‘grapefruit’). The data indicates, however, that this was not common, with the grey set of photographs exhibiting equally high levels of naming accuracy as the colour photographs. The absence of RT differences between the colour and greyscale sets was not expected for naming responses. It is reasonable to assume that colour photographs - with an additional layer of contextual information compared to grey items - would be identified (and therefore named) quicker than grey photographs (e.g. a colour photograph of an orange should avoid the potential ambiguity that might accompany a greyscale depiction, which could initially be confused for another type of fruit). Indeed, Rossion & Pourtois (2004) demonstrated RTs consistent with this hypotheses, with colour drawings showing significantly quicker RTs than grey items. The lack of difference in the current data could be attributable to ceiling effects, whereby all photographs were sufficiently unambiguous, and were quickly identified irrespective of whether they were presented in greyscale or colour. Examination of the other naming data, showing similarly high levels of accuracy and agreement

across grey and colour, supports this notion.

Scores of mental imagery agreement produced particularly interesting results between the grey and colour items. Grey photographs exhibited a significantly poorer match with subjects imagined presentation of the objects than the colour items. Colour differences were not observed previously between drawings (Rossion & Pourtois, 2004), and comparing the current data with that obtained in other studies (see Table 5) demonstrates how the greyscale photographs show uniquely lower mental imagery agreement scores compared with any of the other stimuli formats. To imagine the objects, it seems likely that subjects would conjure an image of how they naturally see the item in their everyday lives - which for the majority of subjects, would presumably be a colour representation. Therefore, when presented with greyscale depictions, subjects may have been more inclined to report that that item did not align quite as well as those presented in colour. However, it is unclear why a similar pattern is not also evident when comparing grey and colour drawings (Rossion & Pourtois, 2004). It may be that photographs promote stricter internal criteria when subjects must decide whether an item is a good match to their mental image. With line-drawn / illustrated items, subjects may simply accept that the items are baseline depictions, and that they will only able to match their real-world mental images to a certain degree - thus leading to a generally more liberal response bias throughout. The addition of colour may therefore do very little to further reconcile the match between the drawing and real-world mental representation. When subjects are responding only to photographs, the ecological nature of the items may facilitate deeper critical evaluation of whether they offer a good match to mental images, and thus promote a more conservative response bias. Colour may therefore be a far more important factor in photographs than it is in line drawings for allowing participants to decide whether an item matches well with their mental image.

There were no colour differences in familiarity scores. This result was expected - participants were asked to rate the degree to which they came in contact with, or think about, the concept itself rather than the particular depiction shown, and there is no apparent reason why colour should influence such ratings. Visual complexity, on the other hand, where participants were required to directly rate the amount of detail in the picture, did show an expected difference. Colour photographs were rated as significantly more visually complex than grey items, presumably due to their additional layer of contextual information. When compared to the previous data obtained for drawings, the greyscale photographs showed comparable levels of visual complexity, while the colour photographs showed higher levels than any of the other formats. It is unclear why the photographs of the current study showed colour differences, when grey and colour drawings did not differ, though it may tie in with the hypotheses proposed to explain the mental imagery agreement data. Subjects may apply stricter internal criteria when rating stimuli that are perceived as being closer to how they would be experienced in real life - when viewing a colour photograph of a rabbit, it is difficult to see how we could make the item any more visually complex than it already is (at least in a 2D medium). It's probable that subjects notice the absence of colour when viewing the greyscale items, since they depict the items in a way that they are not usually seen, and thus determine that these items could be made more complex if they were shown in colour (and so give lower visual complexity ratings as a result).

Establishing a new set of stimuli

The objective of the current study was to establish a new set of ecological photograph stimuli to be taken forward into subsequent recognition memory experiments. Matching items with previously established drawings (and words) would allow for the effects of stimuli-format on recognition response patterns to be directly examined. A range of normative data was collected for 816 unique photograph items. These items may prove useful for a range of cognitive researchers that wish to utilise a set of high quality and realistic object stimuli, especially given the flexibility of items that can be filtered based on colour, naming agreement, familiarity, etc. For the needs of the current body of research, the naming data was used to determine which photographs best matched the intended concepts among a number of possible variations. This allowed for the systematic comparison of recognition memory performance toward three distinct stimuli formats (words, drawings, and photographs) in the following study, in an effort to establish how stimuli of varying perceptual distinctiveness may affect recognition response patterns. Such comparisons might help to reconcile the inconsistencies present across recognition memory research, such as those attempted to determine whether familiarity processes are preserved in those with amnestic Mild Cognitive Impairment (aMCI).

Experiment 3 (Grey drawings + photos)

Effect of stimuli format and response option on recognition memory judgements.

For the recognition memory experiment, everyday objects were presented in three stimuli formats: i) words (written in simple, black ink); ii) drawings (shaded line-drawn illustrations); and iii) photographs (detail rich exemplars of the real world object). Rossion & Pourtois (2004) demonstrated that naming agreement could be improved by adding surface texture and shading to the original Snodgrass & Vanderwart (1980) items; however, it is unclear how manipulations to distinctiveness actually impact performance in recognition memory paradigms. As well as general inconsistencies regarding the type of stimuli used in recognition memory experiments, there is also much variability in the response options available to participants when reporting their recognition, for example: Remember/Know (Lombardi et al. (2016)), Recollection/Familiarity (???), or Low/Med/High confidence (???). In the current experiment, the availability of different response options when reporting recognition will also be examined by randomly assigning participants into a paradigm with three response options (Recollection / Familiarity / Guessing) or four response options (RFG + Both).

Based on the results of Experiment 1, which compared recognition to for words and drawings only, a number of hypotheses are proposed as to the potential effects of adding a third stimuli format (highly distinctive photograph stimuli). As stimuli become increasingly distinctive (from words, to drawings, to photographs), it seems likely that the number of hits (correctly recognised items) will increase, and the number of false alarms (FAs) will decrease. RFG responses are expected to show a similar pattern, with the most detailed stimuli showing the highest number of hits assigned “Recollection”, while the less detailed formats show increasing levels of “Familiarity” and “Guessing” hits. Whilst we expect the overall number of FAs to increase as stimuli become less distinctive (i.e. words will show the highest rate of FAs), there is no reason to believe that these FAs will be biased toward any particular RFG judgement across formats. It is also hypothesised that the rates of reported Recollection and Familiarity will differ across response option conditions (RFG / RFBG), though the direction of this difference is currently unclear.

Method

Participants

A total of 158 subjects completed the online experiment (see Table 6 for a breakdown of the gender and age of the sample). To meet our YA requirements, all participants were required to be between 18-59 years of age (actual range: 18-58). As our experiment involved English word stimuli, we also asked subjects whether English was their first language; the vast majority (95.57%) reported that English was indeed their first language. Subjects were recruited from voluntary participation websites such as Prolific Academic¹⁰ (72.78%), where payment at the rate of £5/hr was given, and via the in-school research participation system¹¹ (15.19%), where they received course participation credits. A small number of participants were also recruited from Psychological Research on the Net¹² (12.03%). In order to detect a medium effect size of Cohen's $f = 0.25$ with 80% power (alpha = .05, two-tailed), G*Power indicated that we would need 79 participants per group ($N = 158$) in a 3x2 mixed ANOVA.

Table 6: Gender and age (SD) of the current sample.

Gender	N	Age	
Female	96	29.53	(10.18)
Male	58	31.36	(11.19)
Questioning	1	21.00	(0)
Unspecified	3	50.33	(4.93)
Total	158	30.54	(10.84)

Materials

A total of 126 innocuous, everyday objects (e.g. clock, rabbit, shoe) were presented across three individual stimuli formats: written words, line drawings, and photographs. The line drawings were obtained from Rossion & Pourtois (2004), and consisted of greyscale shaded illustrations that contained some surface details. The word stimuli were simply the written word names of the line-drawn objects, presented in a clear Sans-serif typeface. The photograph stimuli were curated in the previous study; high quality photographs were sourced to similarly depict the same everyday objects as the line drawings. All objects in the photographs were isolated from their original background, converted to greyscale, and rotated to match the orientations shown in the line-drawn items.

Design

The current study utilised a mixed design, with a 3-level within-subjects factor of stimuli format (words, drawings, photographs), and a 2-level between-subjects factor of response option (RFG, RFBG). Subjects passed through 2 levels of blocked randomization (equally sized, pre-determined blocks); first, participants were randomly assigned one of six possible study lists (of

¹⁰<https://www.prolific.co/>

¹¹<https://keelepsychology.sona-systems.com/>

¹²<https://psych.hanover.edu/research/exponnet.html>

equal length, and containing an even number of word, drawing, and photograph items) for counterbalancing purposes. Subjects were then either assigned into a recognition test with three possible response options (RFG: “Recollection”, “Familiarity”, “Guessing”), or four possible response options (RFBG: “Recollection”, “Familiarity”, “Guessing”, “Both”). These randomisation processes were completed automatically by the experiment software using balanced methods.

Words:	Drawings:	Photographs:

Figure 9: Example stimuli from the three formats.

Procedure

Data was collected online using Gorilla¹³ - a platform for the building and hosting of online experiments. The experiment consisted of three self-paced phases: i) study phase, ii) distractor task, and iii) recognition test. In the study phase, an even mix of word, drawing, and photograph stimuli were presented one-at-a-time on the computer screen. Subjects were instructed to learn the items in preparation for a later memory test. To ensure attention was directed to the presented stimuli, subjects were required to report whether each item was shown as a word, drawing, or photograph using the computer mouse. Following the study phase, participants completed some simple multiple choice mathematical questions (e.g. $6 \times 4 = ?$) as a distractor. Finally, participants memory of the previously studied items was tested in the recognition task. An even mix of word, drawing, and photograph stimuli were again presented one-at-a-time

¹³<https://gorilla.sc/>

on the screen; half of the test items had been shown previously in the study phase, while the other half were new (and were not on the study list). For each item, subjects were instructed to press “Old” if they believed it was an item they had studied earlier, and “New” if they had not. “Old” responses led to a follow-up judgement, where participants reported whether they had experienced recognition through “Recollection”, “Familiarity”, or were simply taking an uninformed “Guess”. Participants that had been randomised into the RFBG test condition had a fourth option here, whereby they could report that they had experienced Recollection and Familiarity simultaneously (“Both”). Stimuli format was congruent across the study and test blocks (e.g. items presented as photos at study were also presented as photos at test). For each concept depicted across the three stimuli formats, subjects were only presented with one variation (in other words, if a subject saw a photograph for the item “shoe”, they did not see the word or line-drawn version of “shoe”).

Data processing

Measured variables included the total number of hits and FAs, and the total number of hits and FAs assigned to each of the available response options (R/F/G and R/F/B/G). In order to create a common dependant variable, proportions were calculated from these variables slightly differently depending on the response option group. In the RFG-judgement group, simple proportions were created from the total number of R responses and the total number of F responses. In the RFBG condition, however, the proportion of Both responses was separately added to R proportions and F proportions. Additional DVs included: i) d' (d-prime, a signal detection measure of sensitivity); ii) c-value (a measure of response bias); iii) overall accuracy (hits / (hits + FAs)); iv) reaction times for all responses.

Participants were excluded from analysis if they showed poor performance during the encoding task; the relative ease of reporting whether each item was shown as a word, drawing, or photograph prompted a performance cut off of 90% accuracy. This allowed for some accidental clicks / incorrect responses toward potentially ambiguous items, though subjects scoring less than 90% were excluded on the assumption they did not dedicate their full attention to the task. Subjects with extreme z-scores were also excluded from analysis; those presenting z-scores of +/- 3 (for total hits, total FAs, or overall recognition [hits minus FAs]) were considered outliers. These criteria resulted in the exclusion of 14 datasets.

Results

A series of 3x2 repeated measures ANOVAs were conducted on each of the DVs using a within-subjects factor of stimuli format (photographs / drawings / words) and a between-subjects factor of response option (RFG / RFBG). Significant main effects and interaction effects were followed-up with Bonferroni-adjusted pairwise comparisons.

Overall hits, false alarms (FAs), and recognition

Separate 3 (stimuli format: words, drawings, photographs) x 2 (response-option condition: RFG-judgements, RFBG-judgements) mixed ANOVAs were conducted on the mean proportion of hits and false alarms (FAs; see Table 7).

Table 7: Mean proportion of hits and FAs by stimuli format and response-option condition.

	Hits	FAs
Stimuli format		
Words	0.55	0.21
Drawings	0.76	0.09
Photographs	0.86	0.05
Response option		
RFG	0.78	0.13
RFBG	0.74	0.11

For the proportion of total hits, there was a significant main effect of stimuli format [$F(1.75, 273.58) = 229.89, MSE = 0.02, p < .001$]. The interaction effect was not significant [$F(1.75, 273.58) = 0.74, MSE = 0.02, p = .461$]. Post-hoc comparisons for the main effect of stimuli format showed that photographs ($M = 0.86$) produced a significantly higher proportion of hits than both words ($M = 0.55$) [] and drawings ($M = 0.76$) []. Drawings ($M = 0.76$) also produced a significantly higher proportion of hits compared to words ($M = 0.55$) [].

There was also a significant main effect of stimuli format for the proportion of total FAs [$F(1.46, 227.29) = 106.64, MSE = 0.01, p < .001$]; photographs ($M = 0.05$) produced a significantly lower proportion of FAs than both words (rexp3_ apa__grey__anova__PROP.FA__words.mean) [] and drawings ($M = 0.09$) []; drawings ($M = 0.09$) produced a significantly lower proportion of FAs compared to words ($M = 0.21$) []. The interaction effect was not significant [$F(1.46, 227.29) = 1.22, MSE = 0.01, p = .287$].

For overall performance accuracy, there was a significant main effect of stimuli format [$F(1.93, 300.97) = 586.13, MSE = 0.02, p < .001$]. The interaction effect was not significant [$F(1.93, 300.97) = 2.02, MSE = 0.02, p = .136$]. Post-hoc comparisons for the main effect of stimuli format showed that photographs ($M = 0.81$) produced significantly better performance accuracy than both words ($M = 0.34$) [] and drawings ($M = 0.67$) []. Drawings ($M = 0.67$) also produced significantly better performance accuracy compared to words ($M = 0.34$) [].

Discrimination (d') and response bias (c)

To assess the roles of discrimination and response bias, separate 3 (stimuli format: words, drawings, photographs) x 2 (response-option condition: RFG-judgements, RFBG-judgements) mixed ANOVAs were conducted on the values of d' (d-prime; measure of sensitivity) and c (decision criterion; see Table 8).

Table 8: d' and c values by stimuli format and response-option condition.

For d' scores, there was a significant interaction between stimuli format and response-option [$F(2.00, 311.73) = 3.60, MSE = 0.26, p = .029$] (see Figure 10). Photographs

	d'	c
Stimuli format		
Words	1.06	0.39
Drawings	2.18	0.32
Photographs	2.78	0.22
Response option		
RFG	0.10	0.01
RFBG	0.10	0.01

($M = 2.86$) facilitated better discrimination between hits / FAs than both words ($M = 1.13$) [$t(312.00) = -21.66, p < .001$] and drawings ($M = 2.13$) [$t(312) = -9.13, p < .001$] in the RFG group. Drawings ($M = 2.13$) also showed significantly higher d' scores compared to words ($M = 1.13$) [$t(312) = -12.53, p < .001$]. In the RFBG group, the same pattern was evident; photographs ($M = 2.69$) facilitated better discrimination than both words ($M = 0.98$) [$t(312) = -20.79, p < .001$] and drawings ($M = 2.24$) [$t(312) = -5.53, p < .001$]. Again, drawings ($M = 2.24$) also showed significantly higher d' scores than words ($M = 0.98$) [$t(319.09) = -10.22, p < .001$].

Comparisons of stimuli format across the response-option groups showed that d' scores for photographs did not significantly differ between the RFG ($M = 2.86$) and RFBG ($M = 2.69$) conditions [$t(319.09) = 1.43, p > .999$], nor for drawings (RFG: $M = 2.13$, RFBG: $M = 2.24$, [$t(319.09) = -0.96, p > .999$]), nor for words (RFG: $M = 1.13$, RFBG: $M = 0.98$, [$t(319.09) = 1.39, p > .999$]).

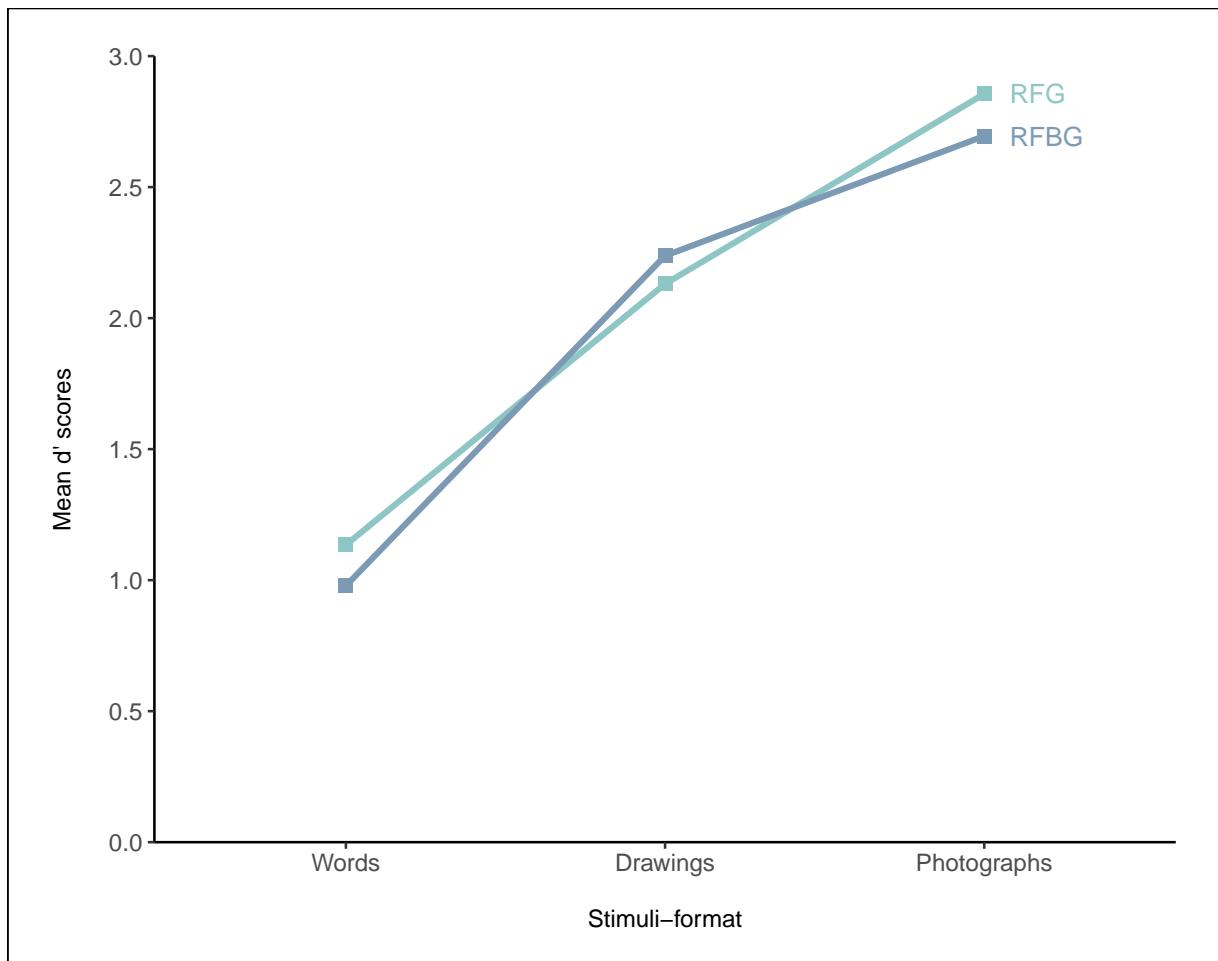

Figure 11: Interaction plot between stimuli format and response-option for d' scores.

c-scores showed a significant main effect of stimuli format [$F(1.74, 272.11) = 10.25, MSE = 0.13, p < .001$], with photographs ($M = 0.22$) demonstrating significantly lower c-scores (and thus a less conservative response bias) than words ($M = 0.39$) [] and drawings ($M = 0.32$). Photographs may have uniquely provided subjects with additional confidence that their old/new response was correct in comparison to the other stimuli formats; there was no difference in c-scores between drawings ($M = 0.32$) and words ($M = 0.39$). There were no significant interaction effects [$F(1.74, 272.11) = 0.62, MSE = 0.13, p = .518$].

Hits assigned Recollection, Familiarity, and Guessing

To determine the effects of stimuli format and response-option on accurate recognition memory judgements, separate 3 (stimuli format: words, drawings, photographs) x 2 (response-option condition: RFG-judgements, RFBG-judgements) mixed ANOVAs were conducted on the mean proportion of hits assigned Recollection, Familiarity, and Guessing (see Figure 12).

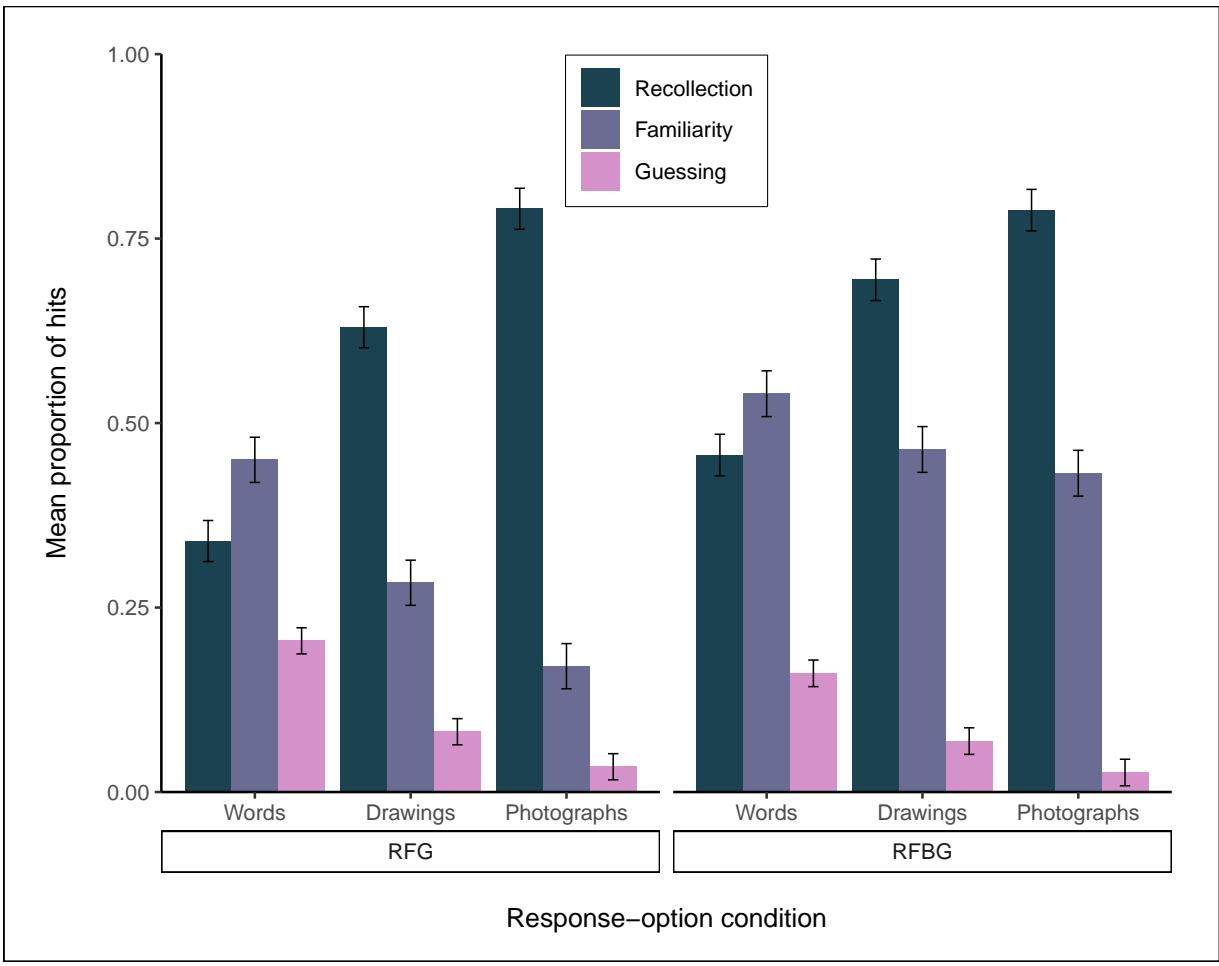

Figure 12: Proportion of hits assigned Recollection, Familiarity, and Guessing, by stimuli format and response-option condition.

Recollection (hits) For hits assigned Recollection, there was a significant interaction effect [$F(1.77, 273.98) = 5.32, MSE = 0.03, p = .007$] (see Figure 13). Photographs ($M = 0.79$) resulted in more Recollection hits than both words ($M = 0.34$) [$t(310) = -17.90, p < .001$] and drawings ($M = 0.63$) [$t(310) = -6.38, p < .001$] in the RFG group. Drawings ($M = 0.63$) also resulted in more Recollection hits than words ($M = 0.34$) [$t(310) = -11.52, p < .001$] in the RFG group. In the RFBG group, there was an identical pattern; photographs ($M = 0.79$) resulted in more Recollection hits than both words ($M = 0.46$) [$t(310) = -12.62, p < .001$] and drawings ($M = 0.69$) [$t(310) = -3.59, p = .006$]. Drawings ($M = 0.69$) also resulted in more Recollection hits than words ($M = 0.46$) [$t(310) = -9.03, p < .001$] in the RFBG group. Comparisons of stimuli format across the response-option groups showed no difference in the number of Recollection hits for photograph stimuli between the RFG ($M = 0.79$) and RFBG ($M = 0.79$) conditions [$t(278.97) = 0.05, p > .999$]. The same pattern was evident for drawings (RFG: $M = 0.63$, RFBG: $M = 0.69$ [$t(278.97) = -1.62, p > .999$]). Word stimuli, however, produced significantly more Recollection hits in the RFBG group ($M = 0.46$) compared to the RFG ($M = 0.34$) group.

$[t(278.97) = -2.94, p = .053]$.

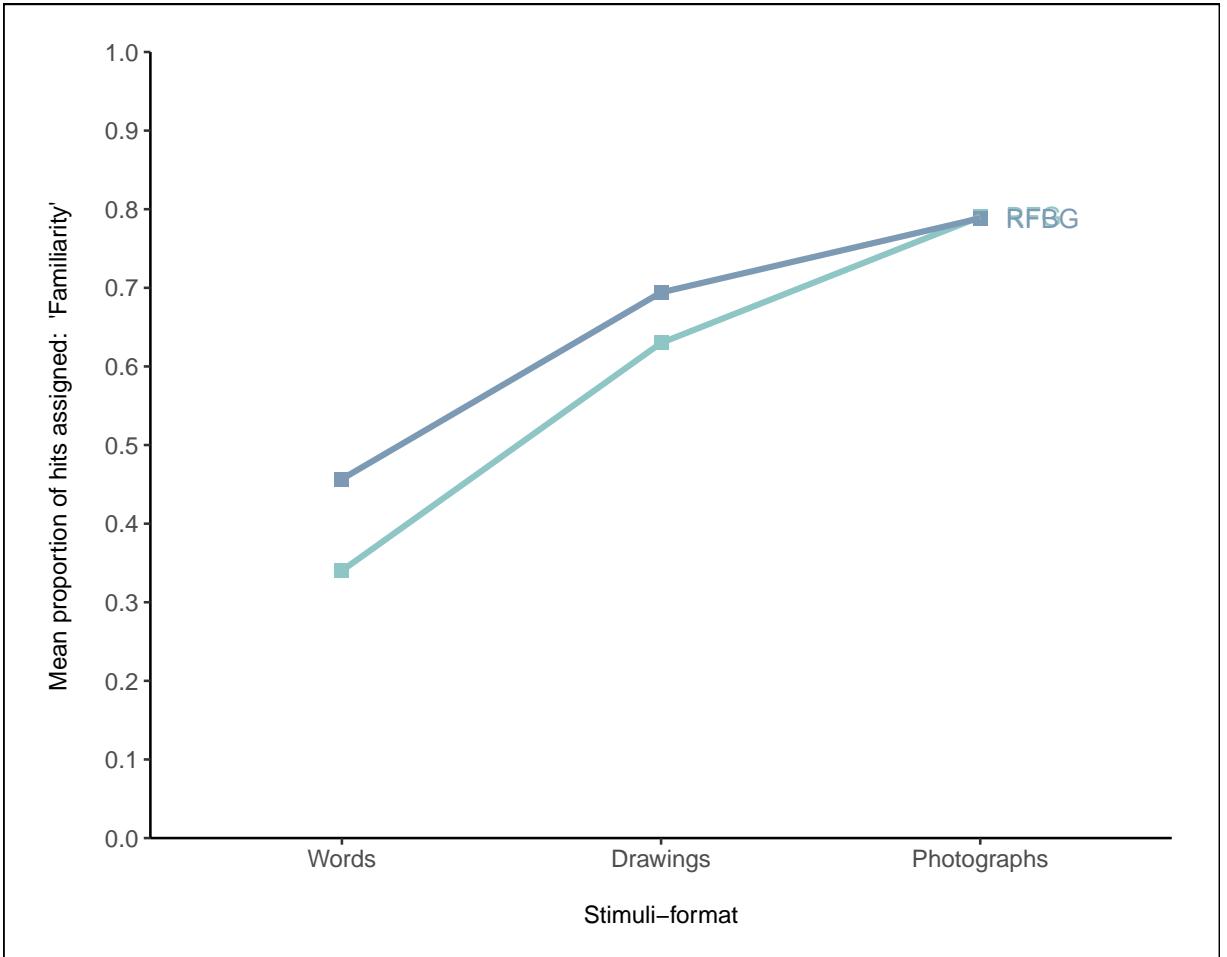

Figure 13: Interaction plot between stimuli format and response-option for the mean proportion of hits assigned Recollection.

Familiarity (hits) For hits assigned Familiarity, there was a significant interaction between stimuli format and response-option [$F(1.52, 236.21) = 8.68, MSE = 0.04, p = .001$] (see Figure 14). Within the RFG condition, words ($M = 0.45$) resulted in more Familiarity hits than both drawings ($M = 0.28$) [$t(310) = 5.84, p < .001$] and photographs ($M = 0.17$) [$t(310) = 9.80, p < .001$]. Drawings ($M = 0.28$) also produced more Familiarity hits compared to photographs ($M = 0.17$) [$t(310) = 3.96, p = .001$].

Within the RFBG condition, words ($M = 0.54$) still produced more Familiarity hits than photographs ($M = 0.43$) [$t(310) = 3.61, p = .005$]. However, there was no difference in the number of Familiarity hits when comparing words ($M = 0.54$) to drawings ($M = 0.46$) [$t(310) = 2.53, p = .178$]. Another difference from the within-RFG findings is the number of Familiarity hits for drawings ($M = 0.46$) did not differ from photographs ($M = 0.43$) in the RFBG condition [$t(310) = 1.08, p > .999$].

Comparisons across response-option conditions showed that drawings produced significantly more Familiarity hits in the RFBG ($M = 0.46$) condition compared to RFG ($M = 0.28$) [$t(289.15) = -4.14, p = .001$]. A similar pattern was also evident for photographs (RFG: $M = 0.17$, RFBG: $M = 0.43$ [$t(289.15) = -6.00, p < .001$]). Words, however, showed no difference in the number of Familiarity hits between the RFG ($M = 0.45$) and RFBG ($M = 0.54$) conditions [$t(289.15) = -2.06, p = .611$].

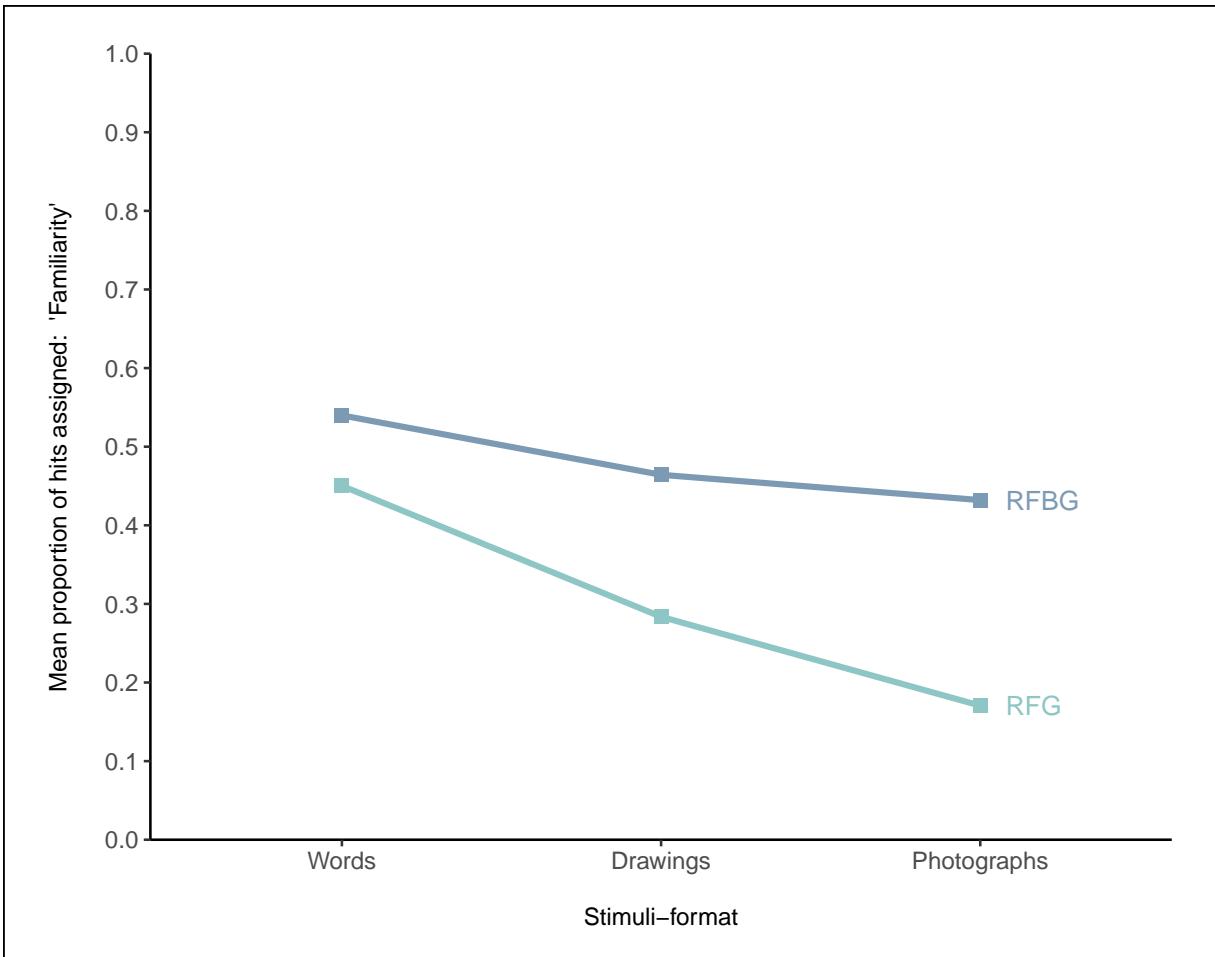

Figure 14: Interaction plot between stimuli format and response-option for the mean proportion of hits assigned ‘Familiarity’.

Guessing (hits) For hits assigned Guessing, there was a significant main effect of stimuli format [$F(1.32, 204.20) = 71.22, MSE = 0.02, p < .001$]. The interaction effect was not significant [$F(1.32, 204.20) = 1.12, MSE = 0.02, p = .308$]. Post-hoc comparisons for the main effect of stimuli format showed that words ($M = 0.18$) produced significantly more Guessing hits than both drawings ($M = 0.08$) [] and photographs ($M = 0.03$) []. Drawings ($M = 0.08$) also produced significantly more Guessing hits compared to photographs ($M = 0.03$) [].

FAs assigned Recollection, Familiarity, and Guessing

To determine the effects of stimuli format and response-option on false alarms, separate 3 (stimuli format: words, drawings, photographs) \times 2 (response-option condition: RFG-judgements, RFBG-judgements) mixed ANOVAs were conducted on the mean proportion of FAs assigned Recollection, Familiarity, and Guessing (see Figure 15).

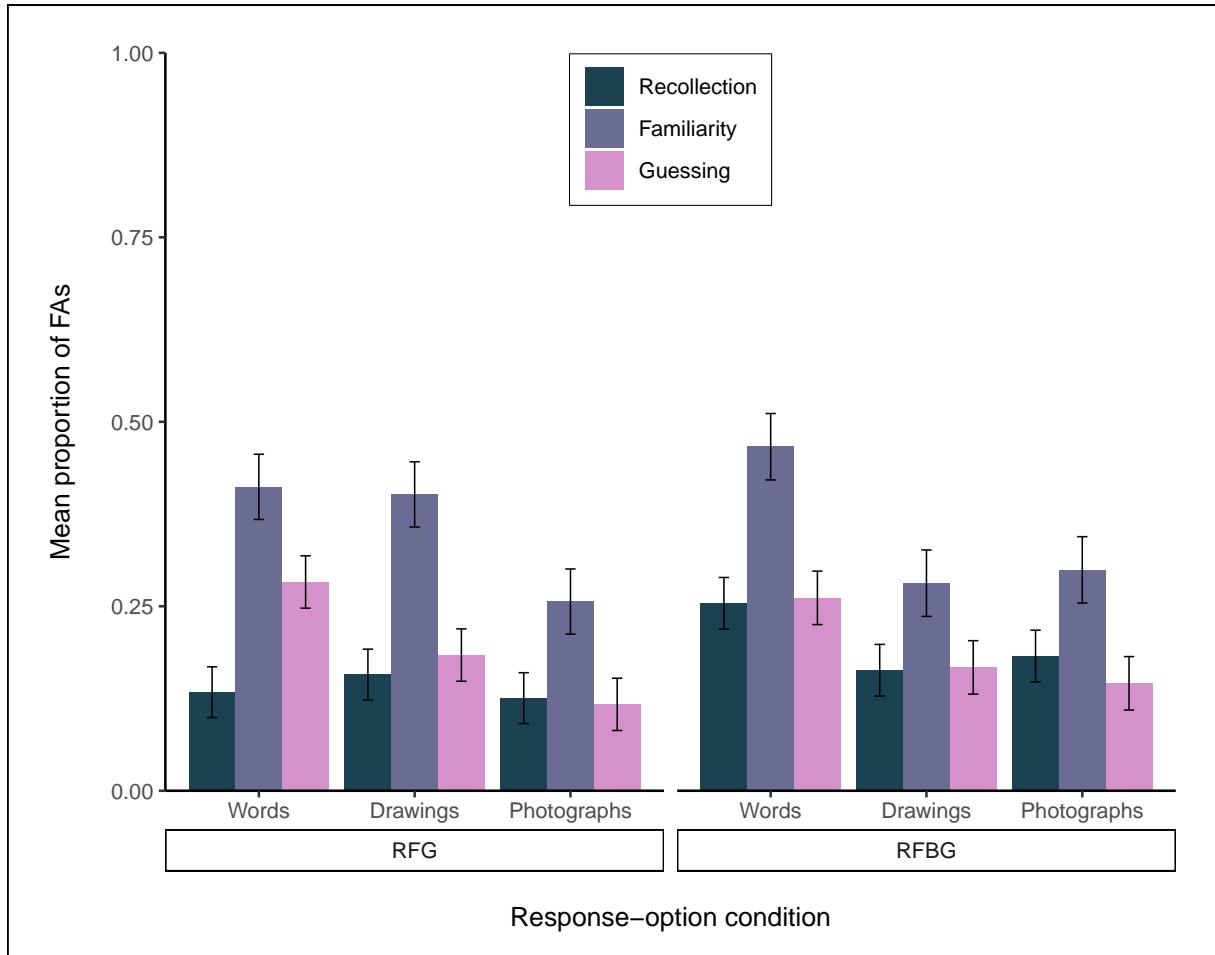

Figure 15: Proportion of FAs assigned Recollection, Familiarity, and Guessing, by stimuli format and response-option condition.

Recollection (FAs) For FAs assigned Recollection, there was no significant main effect of stimuli format [$F(1.94, 301.96) = 1.11, MSE = 0.07, p = .328$] or interaction [$F(1.94, 301.96) = 2.02, MSE = 0.07, p = .136$].

Familiarity (FAs) For FAs assigned Familiarity, there was a significant interaction between stimuli format and response-option [$F(1.98, 309.33) = 3.33, MSE = 0.11, p = .038$] (see Figure 16). Within the RFG condition, words ($M = 0.41$) resulted in more Familiarity FAs than photographs ($M = 0.26$) [$t(312) = 2.96, p = .050$], but not drawings ($M = 0.40$)

$[t(312) = 0.20, p > .999]$. The number of Familiarity FAs did not differ between drawings ($M = 0.40$) and photographs ($M = 0.26$) [$t(312) = 2.76, p = .091$] in the RFG condition.

Within the RFBG condition, words ($M = 0.47$) again produced more Familiarity FAs than photographs ($M = 0.30$) [$t(312) = 3.06, p = .036$]. However, words ($M = 0.47$) also produced more Familiarity FAs than drawings ($M = 0.28$) [$t(312) = 3.39, p = .012$]. As before, the number of Familiarity FAs did not differ between drawings ($M = 0.28$) and photographs ($M = 0.30$) in the RFBG condition [$t(312) = -0.33, p > .999$].

Comparisons across response-option conditions showed no differences in the number of Familiarity FAs, for any stimuli format: words (RFG: $M = 0.41$, RFBG: $M = 0.47$ [$t(404.98) = -0.86, p > .999$]); drawings (RFG: $M = 0.40$, RFBG: $M = 0.28$ [$t(404.98) = 1.91, p = .859$]); photographs (RFG: $M = 0.26$, RFBG: $M = 0.30$ [$t(404.98) = -0.68, p > .999$]).

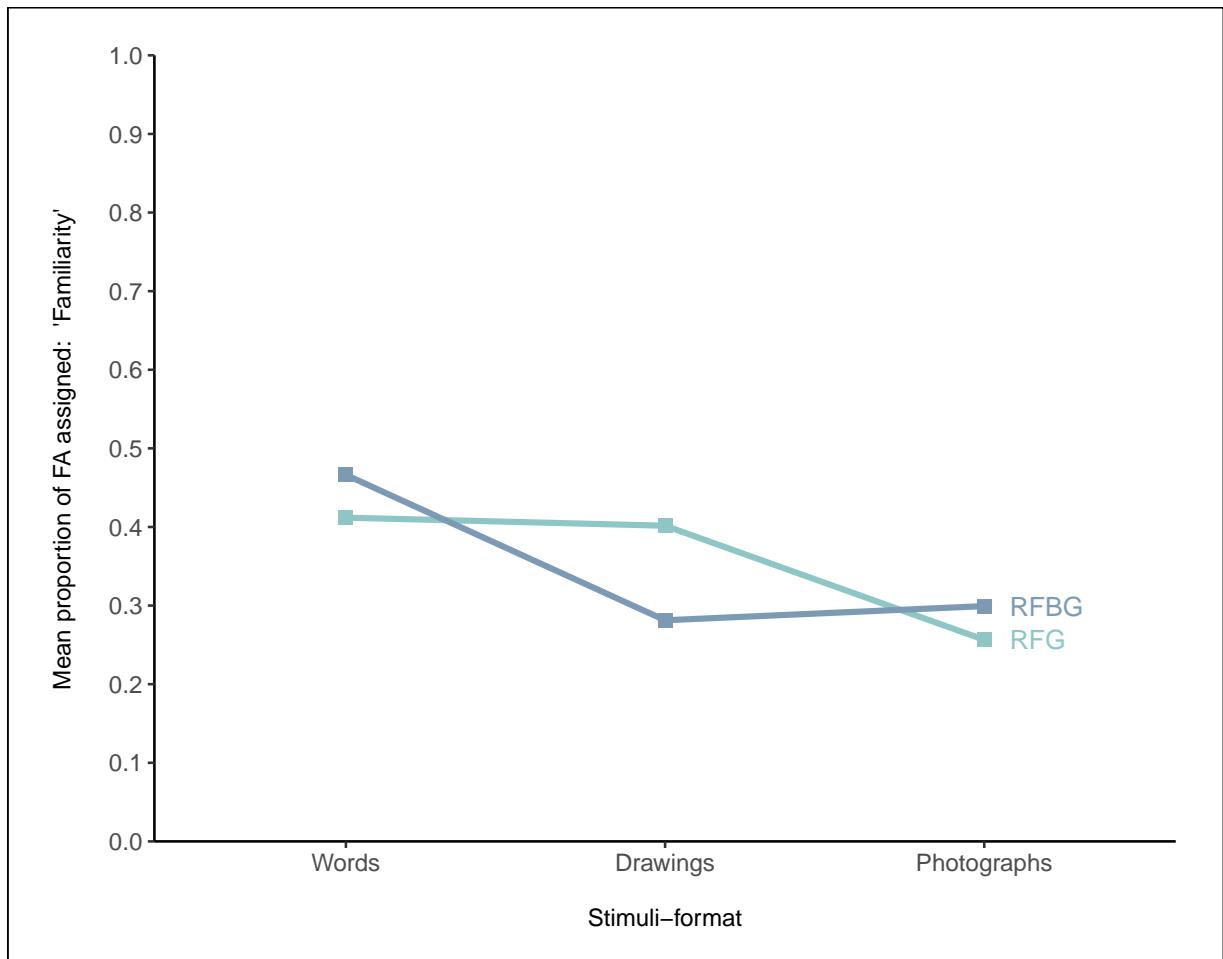

Figure 16: Interaction plot between stimuli format and response-option for the mean proportion of FAs assigned ‘Familiarity’.

Guessing (FAs) For FAs assigned Guessing, there was a significant main effect of stimuli format [$F(1.93, 300.68) = 9.44, MSE = 0.09, p < .001$]. The interaction effect was not significant [$F(1.93, 300.68) = 0.35, MSE = 0.09, p = .699$]. Post-hoc comparisons for the main effect of stimuli format showed that words ($M = 0.27$) produced significantly more Guessing FAs than both drawings ($M = 0.18$) [] and photographs ($M = 0.13$) []. There was no difference in the proportion of FAs assigned Guessing between drawings ($M = 0.18$) and photographs ($M = 0.13$) [].

Discussion

Across a range of performance variables, the results show a clear effect of stimuli distinctiveness. As distinctiveness increased (from words, to drawings, to photographs), this produced more hits, less FAs, better overall recognition, and better discrimination between hits / FAs. The absence of any interaction effects across these variables demonstrates that the availability of different response options (i.e. the addition of a Both option) had little impact on overall performance. RF(B)G responses for accurate recognition displayed a similar pattern; as distinctiveness increased, the number of Recollected hits also increased, while the number of Familiarity and Guessing hits decreased. The rate of both Familiarity FAs and Guessing FAs was also highest for the least distinctive stimuli (words).

Chapter 4 (Addition of colour)

Chapter 5 (Addition of colour)

Method

All stimuli were presented as 500x500px image files at their actual size (i.e. without scaling) to ensure consistency across participants. Adobe Photoshop 2021 (22.0.0 Release) was used to create the image files, all on a plain white canvas. The Rossion and Pourtois (2004) line-drawings were sourced directly from the authors, and were trimmed of any preexisting background before being resized to fit the 500x500px canvas (for some items this was determined by a maximum width of 500px, whilst for others it was determined by a maximum height of 500px).

word stimuli were created in Roboto (light, 54pt)

Appendix B

Table 10: Normative data for all photograph items.

Photograph	Familiarity	Visual Complexity	Colour Diagnosticity	Mental Imagery
anchor				
anchor1-photo-colour	3.55 (1.32)	3 (1.11)	2.77 (1.19)	4.05 (1.05)
anchor1-photo-grey	3.03 (1.47)	2.81 (0.93)		3.95 (0.89)
anchor2-photo-colour	3.38 (1.56)	3.45 (1.23)	3.5 (1.19)	3.75 (1.25)
anchor2-photo-grey	2.82 (1.53)	3 (0.97)		3.52 (1.33)
anchor3-photo-colour	3.5 (1.3)	2.48 (0.93)	2.76 (1.3)	3.86 (1.01)
anchor3-photo-grey	3.04 (1.43)	2.46 (1.22)		4.27 (0.77)
apple				
apple1-photo-colour	4.8 (0.48)	3.1 (1.14)	3.43 (1.08)	4.15 (0.88)
apple1-photo-grey	4.85 (0.49)	2.32 (1.21)		3.05 (1.23)
apple2-photo-colour	4.91 (0.29)	3 (0.97)	3.5 (1.32)	3.76 (1.04)
apple2-photo-grey	4.24 (1.14)	2.4 (0.99)		2.75 (1.45)
apple3-photo-colour	4.77 (0.53)	3.16 (1.37)	3.68 (1.25)	4.27 (0.98)
apple3-photo-grey	4.73 (0.63)	2.38 (1.07)		3.38 (1.28)
ashtray				
ashtray1-photo-colour	3.77 (1.43)	3.05 (1.16)	2.71 (1.1)	3.9 (1.07)
ashtray1-photo-grey	4.15 (1.14)	2.95 (1.13)		3.5 (1.28)
ashtray2-photo-colour	3.86 (1.46)	3 (1.08)	2.25 (1.29)	4.1 (1.3)
ashtray2-photo-grey	3.52 (1.47)	3 (1.12)		3.5 (1.28)
ashtray3-photo-colour	3.36 (1.47)	3.75 (1.15)	3.21 (1.32)	3.5 (1.19)
ashtray3-photo-grey	4.14 (0.99)	3.09 (1.11)		3.76 (1)
balloon				
balloon1-photo-colour	4.4 (1.1)	1.63 (1)	2.35 (1.69)	4.62 (0.92)
balloon1-photo-grey	4.15 (1.18)	1.8 (1.11)		3.41 (1.1)
balloon2-photo-colour	4.45 (1)	2.14 (1.08)	1.82 (1.3)	4.5 (1)
balloon2-photo-grey	4.35 (0.81)	1.9 (1)		4.05 (0.94)
balloon3-photo-colour	4.09 (1.02)	1.86 (1.04)	1.86 (1.49)	4.46 (0.88)
balloon3-photo-grey	4.24 (0.94)	1.68 (0.99)		3.57 (1.4)
banana				
banana1-photo-colour	4.65 (0.99)	2.55 (1.5)	4.55 (0.76)	4.45 (0.86)
banana1-photo-grey	4.8 (0.7)	2.23 (1.1)	2.36 (1.5)	3.76 (0.94)
banana2-photo-colour	4.8 (0.41)	2.05 (1.24)	4 (1.3)	4.85 (0.37)
banana2-photo-grey	4.9 (0.45)	2.36 (1.36)		3.3 (1.42)
banana3-photo-colour	4.33 (1.02)	2.05 (1.09)	4.59 (0.96)	4.67 (0.66)
banana3-photo-grey	4.86 (0.47)	2 (0.87)		3.58 (1.1)
barrel				
barrel1-photo-colour	3.53 (1.25)	3.57 (0.93)	3.95 (0.97)	4.9 (0.45)
barrel1-photo-grey	3.9 (1.29)	3 (1.02)		4.05 (1.05)
barrel2-photo-colour	4 (1.02)	3 (1.08)	3.5 (1.15)	4.43 (0.81)
barrel2-photo-grey	3.81 (1.54)	2.95 (1.1)		4.15 (0.93)
